Background: Combinations of minimally invasive procedures (MIPs) are often used in aesthetic treatments and are increasingly considered as the new standard of care. Three agents with specific properties are available in this perspective: a polycaprolactone (PCL)-based collagen stimulator, a poly-L-lactic acid (PLLA)- and a poly-glycolic acid (PLGA)-based resorbable suspension suture with a 3D-cone technology, and a cross-linked hyaluronic acid (HA).

Objective: To develop the first practice guidelines on rejuvenation treatment of the face and the neck using combinations of these agents, whether associated or not with other widely used MIPs such as botulinum neurotoxins or energy-based devices.

Methods: A multi-disciplinary, multi-national board of plastic surgeons and dermatologists convened to develop guidelines using a predefined consensus method. The consensus was defined as $\geq 83\%$ agreement rate between participants.

Results: Practice guidelines and algorithms, describing optimal procedure sequence and spacing, are proposed for the treatment of upper-, mid-, lower-face and neck, combining the PCL collagen stimulator, the PLLA/PLGA suspension sutures, and the cross-linked HA, whether associated or not with other MIPs.

Conclusion: These new guidelines provide general support to optimal management strategies. Individual treatment plans should be adapted according to the physician's individual competence and the patient's preferences.

Keywords: botulinum toxins, combined modality therapy, dermal fillers, energy-based device, practice guideline, rejuvenation

Introduction

Since the appearance of skin and face are considered important factors of well-being and health, the number of aesthetic procedures performed worldwide is continuously increasing.^{1,2} For instance, according to the American Society of Plastic Surgeons, 17.7 million surgical and minimally invasive cosmetic procedures were performed in the United States (US) in 2018.³

In this context, the use of minimally invasive procedures (MIPs) increased strongly by +228% growth rate between years 2018 and 2000 in the US,³ and MIPs represent now nearly 90% of aesthetic interventions.⁴ They aim to attain optimal results with minimal invasiveness, faster recovery, reduced scarring, limited

stress, and better patient satisfaction.⁵ They include a wide range of injectable agents, devices, and techniques, each being performed in precise indications. The most often used injectable agents are the *Clostridium botulinum*-derived botulinum neurotoxins (BoNTx), which induce a temporary relaxation of muscles,⁶ and hyaluronic acid-based (HA) biodegradable soft-tissue fillers.^{7,8} Other biodegradable fillers, based on calcium hydroxylapatite (CaHA), polycaprolactone (PCL) or poly-L-lactic acid (PLLA), possess additional bio-stimulatory properties.^{9–11} The term “energy-based devices” (EBDs) encompasses different purposes and devices, ie, tightening (micro modelling) vs resurfacing techniques. Commonly used EBDs in face and neck rejuvenation are radio frequency (RF) for skin tightening and collagen contraction, skin resurfacing lasers, and high-intensity focused ultrasound (HIFU) for wrinkle reduction and skin tightening.^{6,12–15} While mechanical liposuction and chemical lipolysis are used for fat reduction, intense pulsed light (IPL) is used for improving skin colour and texture.

Combination Treatments: The New Standard of Care

MIPs are increasingly utilised in combination protocols to improve outcomes.¹⁶ In 2014, nearly half of all aesthetic patients in the US who requested MIPs received multiple procedures.⁴ Indeed, combination treatments offer an optimal response to the multifactorial process of facial ageing, which involves structural changes in all anatomical layers (bone, muscles, ligaments, adipose tissue, and skin) and dynamic interactions among these tissues.^{2,17,18} Consequently, the modern concept of natural and harmonious rejuvenation is based on a comprehensive, three-dimensional, multi-layered approach, combining multiple agents and techniques to attain multiple goals such as relaxation, volumisation, volume repositioning, reshaping, resurfacing, or tightening, depending on specific patient needs.^{6,17,19}

Diverse multimodal approaches have been assessed for face and neck rejuvenation in clinical studies (Table 1). The studies have generally concluded that combination treatments display additive or even synergistic effects, leading to better and longer-lasting results compared to single agent- or single technique-based protocols, with no clinical evidence of increased adverse events (AEs) rate or severity.^{6,16,20–22} Therefore, combined treatments are now considered the new standard of care.¹⁸

PCL Collagen Stimulator, PLLA/PLGA Suspension Sutures, Cross-Linked HA

Three distinct agents have been proposed by a single company (Sinclair Pharmaceuticals, London, UK) for minimally invasive rejuvenation treatments: a biodegradable collagen stimulator (Ellanse[®]), a resorbable suspension suture with a 3D-cone technology (Silhouette Soft[®]), and a cross-linked HA (Perfectha[®]).

The collagen stimulator is composed of bioresorbable PCL microspheres suspended in an aqueous carboxymethylcellulose gel carrier. In addition to their soft-tissue filler effect, the microspheres stimulate the production of new collagen,^{11,23} resulting in volume restoring, face

reshaping, and skin quality improvement. Three versions are available (Ellansé-S®, -M®, -L®), providing the duration of effect from at least 18 months up to 3 years (Table 2),^{24,25} as the degradation time of the PCL microspheres depends on the initial polymer chain length.^{26–28} Clinical studies, including prospective randomized controlled trials (RCTs), have shown product safety and efficacy in the treatment of nasolabial folds,^{29,30} forehead augmentation,³¹ hand rejuvenation,³² and complete facial rejuvenation.³³ Consensus guidelines stated that this PCL collagen stimulator offers noteworthy advantages over PLLA-based fillers, as the results are immediately visible, and over HA- and CaHA-based fillers, due to better stability and duration of the results.³⁴ A worldwide post market survey (2012–2019) found a 0.0562% AEs rate, confirming excellent safety in daily practice.³⁵

The suspension sutures are made of PLLA biodegradable monofilaments that support resorbable 3D cones made of a copolymer of PLLA and poly-glycolic acid (PLGA). These unique features lead to a dual effect: an immediate repositioning of the sagging tissue and, thanks to the collagen stimulation, a gradual and sustained tissue regeneration. The sutures are utilised in the treatment of mild to moderate skin sagging on the mid-face, lower face, full face, neck, and in eyebrow repositioning. Three product references are available (8 cones, 12 cones, and 16 cones) to address different areas and degrees of skin laxity. Clinical studies have shown the efficacy of these threads as well as their long-lasting effect and safety, with the observed AEs being mild to moderate and easily manageable.^{36–38} A post market survey (2012–2019) found a very limited 0.0231% overall AEs

rate.³⁹ A recent US-based expert consensus concluded that the treatment with absorbable facial suspension sutures, when performed properly, is associated with minor and infrequent AEs, offering a beneficial clinical alternative to traditional facial rejuvenation techniques.⁴⁰

The third product range includes resorbable high molecular weight and high purity HA gels of non-animal origin which are cross-linked with butanediol diglycidyl ether. Five different versions are available. All the products of the range have the same HA concentration (20mg/mL), but their particle sizes and rheological properties vary: the bigger the particles, the greater the volumizing effect and the longer-lasting the results. Thus, each gel is different and designed to best meet specific needs, depending on the area to be treated, the volume needed, and the depth of injection required. As a consequence, these agents are utilised in a wide range of rejuvenation treatments: from superficial or deep lines filling to volume creation and contour shaping.^{41,42} Clinical studies have shown their efficacy, lasting for six to 18 months, as well as a high level of patient and physician satisfaction.^{43–46} Devoid of inflammatory effects,⁴⁷ these cross-linked HA gels are safe in daily clinical use as evidenced by a post market survey (2012–2019) that found a 0.0239% AEs rate out of 2.8 million syringes sold worldwide.⁴⁸

In daily practice, the PCL collagen stimulator, the PLLA/PLGA suspension sutures, and the cross-linked HA are most often combined in multimodal rejuvenation protocols. As no specific recommendations existed to guide this frequent practice, the objective of the present work was to provide physicians with guidelines on the optimal use of these agents in combination in face and neck rejuvenation treatments.

Methods

The guidelines were developed by a multi-disciplinary, multi-national board of plastic surgeons and dermatologists representing a worldwide perspective. As an initial step, each participant was asked to independently indicate personal preferences concerning the best-combined rejuvenation treatment of predefined target areas (neck, lower face, mid-face, and upper face) using a common standardized questionnaire. Participants were also asked to analyse frequent aesthetic problems separately within each area (eg, for lower face: loss of jawline contour, loss of submental cervical angle, and so on) in patients with mild or moderate to severe signs of aging. Individual preferences were compiled in anonymised summary tables, which were presented for discussion at a consensus meeting. All options were submitted to plenary votes to identify formal consensual statements according to the following criteria:

1. Agreement of six out of six experts: strong consensus,
2. Agreement of five out of six experts (83% agreement): consensus,
3. Agreement of $\leq$ four/six experts: absence of consensus.

Results and Recommendations

The board commented on the initially proposed analytical approach, objecting that the adjectives “mild”, “moderate”, and “severe” are vague and subjective: a patient may well be sorted in different categories by different physicians. Thus, this approach cannot be used unless based on a validated and widely accepted (visual) scale. Moreover, differences in patient management according to severity are often only a matter of the number of sessions and product amounts, not different strategies. The focus on individual aesthetic unit problems within the same face area appeared superfluous and irrelevant: in daily practice, most patients are treated by combination protocols for more than one mutually correlated aesthetical problems within the same area.

However, a series of key orientations to categorize the usual problems and manage combination treatments were consensually agreed.

Guidelines on Common Key-Principles

It is not advisable to perform multiple procedures on the same area during the same session because scant data are available on possible interactions, making it difficult to

accurately incriminate the responsible agent/procedure in case of an emergent AE. However, the board members acknowledged that they do not always follow this rule, assuming thereby increased personal responsibility and that no complications may arise from combining different treatment modalities in different anatomical areas during the same session.

As a rule, the rejuvenation protocol should successively aim for two main objectives: volume adjustment (reduction, replacement/augmentation or creation) in the first place, tissue reposition afterwards. A frequently needed optional final step aims at improving the overall result performing “touch up” and skin quality improvement procedures. Regarding volume replacement, the board favours the PCL collagen stimulator, as it offers an additional long-term rejuvenating effect by stimulating neocollagenesis, but HA fillers, as per the treating physician preference, can also be used.

Volume (fat) reduction can be performed by any physician’s preferred usual technique (laser-assisted lipolysis, chemical lipolysis solution, liposuction, HIFU). Most board members recommend performing fat-reduction before PLLA/PLGA sutures insertion (respecting an interval of six to eight weeks after injection lipolysis, and a 12-week interval after liposuction or cryolipolysis); one participant prefers applying injection lipolysis two weeks after sutures insertion.

The PLLA/PLGA suspension sutures should be placed according to the currently recommended straight patterns, strictly avoiding the “U” and the angle (“L”) patterns. The number of sutures implanted in every target area should be sufficient to induce optimal effect and patient satisfaction.

BoNTx injections are always recommended for eye-brows and neck rejuvenation, where they should be performed two weeks before the PLLA/PLGA sutures insertion, since complete muscular relaxation allows better cones encapsulation and a more stable effect (see the “blanket statement” in Table 3). Their use is optional in other areas where they are often injected before or during the same session as volume replacement.

The cross-linked HA fillers or the PCL collagen stimulator may also be injected as an elective last step, designed to improve the final result, thanks to a “touch up” effect, ie, fine-line/wrinkle correction, skin quality improvement and beautification (eg, lip enhancement/augmentation, additional volume augmentation, and so on).

Table 3 Focus on Important Treatment Spacing Principles

<p>Combined Use of EBDs and PLLA/PLGA Suspension Sutures</p> <ul style="list-style-type: none"> EBD tightening techniques should be used 6–8 weeks before (preferably) or 8–12 weeks after the PLLA/PLGA sutures insertion. Resurfacing techniques should be performed 2–4 weeks before or after (preferably) the PLLA/PLGA suspension sutures insertion.
<p>Combined Use of BoNTx and PLLA/PLGA Suspension Sutures</p> <ul style="list-style-type: none"> BoNTx injection should be performed 2 weeks before PLLA/PLGA sutures insertion.
<p>Optional Touch Up Treatment</p> <ul style="list-style-type: none"> Should be injected 4–6 weeks after initial volume replacement/augmentation when using the PCL collagen stimulator; or 2 weeks after initial filler treatment when using the cross-linked HA.

Abbreviations: BoNTx, botulinum neurotoxin; EBD, energy-based device; HA, hyaluronic acid; PLLA/PLGA, poly-L-lactic acid/poly-glycolic acid.

EBD Use

Some EBD tightening techniques (eg, RF, US) may interfere with the fillers and the PLLA/PLGA sutures and impair the subsequent collagen production: It is thus recommended to perform them on separate sessions. They should preferably be performed before (6–8 weeks) the insertion of the PLLA/PLGA sutures: The key reason is that this period is needed to start collagen remodeling, resulting in better support for PLGA cones of the suspension sutures. If EBD tightening techniques are performed after suture insertion or filler injection, the interval should be longer (eight–12 weeks) to avoid the risk of suture breakage or filler meltdown.

When applied, EBD resurfacing techniques should preferably follow the PLLA/PLGA suspension sutures insertion (after a two–four-week interval). If resurfacing is performed before, the skin should be properly re-epithelialized (healed) and made free of any resurfacing-associated complication or AEs (bacterial or viral infection, delayed healing areas) before suture insertion.

EBD techniques may be used at any of the above-cited locations in addition to other more area-specific treatments.

Algorithms According to Treatment Areas

Area-specific treatment algorithms were developed according to the key-principles described above and accounting for the usual area-specific rejuvenation priorities. To keep this report adequately concise, the proposed treatment sequences and spacings are specified in relevant figures, while the text highlights only some conceivable alternatives or noticeable comments.

Upper Face

The overall upper-face rejuvenation procedure (sequence and spacing) was agreed with a strong consensus level. It starts with systematic BoNTx injections, associated with volume replacement. The sequence then differs depending on whether further tissue reposition (eyebrows elevation) is based on either cross-linked HA or PCL collagen stimulator injections (Figure 1A) or on 8-cone PLLA/PLGA sutures insertion (Figure 1B). The final touch-up/refinement session is optional.

Mid-Face

Mid-face rejuvenation treatment starts with volume replacement, followed by tissue reposition (Figure 2); agreement level: strong consensus. The third “touch up” step is optional and should not be performed before the results of the previous steps are stabilized.

Lower Face

The overall lower-face rejuvenation procedure, starting with volume adjustment (reduction or replacement/augmentation) is described in Figure 3. A minor discrepancy existed between board members regarding the preferred sequence of injection lipolysis and the PLLA/PLGA sutures insertion: starting with injection lipolysis was the consensually adopted choice, but one participant preferred the reverse sequence; (overall agreement level: consensus). The BoNTx-based muscular relaxation (“Nefertiti lift”^{49,50}) is optional and, when needed, should be separated by a two-week interval with the next step (tissue reposition, suture insertion). The last (fourth) “touch up” step is also optional.

Neck

The two- to four-step neck rejuvenation treatment may start with either an optional volume reduction, an optional EBD tightening or a systematic BoNTx-based platysma relaxation (Figure 4); overall agreement level: consensus. When performed, the EBD tightening should be separated by a long enough interval with the PLLA/PLGA sutures insertion (tissue reposition). Finally, an optional fifth step (dermal filler injections according to its instructions for use, two weeks after sutures insertion) may be needed to perfect the results.

Discussion

We propose here the first recommendations on the multimodal rejuvenation treatment of the face and neck involving three specific agents, ie, the PCL collagen

A

stimulator, the PLLA/PLGA suspension sutures, and the cross-linked HA. Such recommendations are needed because previously published consensuses have been focused on the separate use of the PCL collagen stimulator³⁴ or the PLLA/PLGA suspension sutures only,⁴⁰ while combination treatments are commonly used in daily practice and may lead to serious problems

if followed inappropriate sequencing or spacing (eg, unfavourable interaction between EBD techniques and the PLLA/PLGA sutures). We believe that our recommendations are reliable as they are designed by a multi-disciplinary group of experienced physicians, are based on a formal consensus method, and only propose attitudes supported by a high agreement rate. However, the

US-based board member could not directly comment on the fillers that are not approved by the Food and Drug Administration (FDA) but extrapolated recommendations from the use of FDA-approved fillers. Finally, our recommendations account for a wide range of other commonly used agents and techniques, rendering them probably relevant and helpful in daily practice.

We have deliberately designed our consensus as general guidelines on the best management strategy and not as detailed recommendations on precise problems. This is because the addressed practice field encompasses nearly an infinite number of individual problems. Like all other authors, we acknowledge that such guidelines are never enough – they provide only general support, not an individualized treatment plan.⁶ The optimal treatment plan always results from a physician's individual knowledge (anatomy, aging physiology, product characteristics), training (injection or insertion techniques), general clinical competence, responsibility, and wisdom combined with the patient's values and preferences.^{17,34}

Comparable consensus guidelines have also most often specified their recommendation according to separate areas (eg, upper, mid-, and lower face, neck), the type of injected agents or EBDs, and the treatment sequence and timing (Table 4).^{6,18,51} The importance of spacing different treatments (at least one to two weeks)

on the same area was generally highlighted to allow the resolution of local side-effects and reliably assess efficacy results and potential AEs.^{6,51} While some injectable agents (BoNTx, HA, CaHA) can safely be used on the same day and in any sequence, EBDs (MFU-V) should be delivered on a separate occasion, preferably before filler injection.^{6,18,51}

The main limitations of our guidelines pertain to the drawbacks associated with the expert consensus method and the lack of population specificity. Indeed, it has been emphasized that ethical guidelines should be evidence-based, ie, derived from randomized controlled trials (RCTs) and meta-analyses of RCTs, which bear low risk for bias.¹ However, RCTs are very rare in the rejuvenation and beautification domain, especially regarding multi-modal management.⁵² Thus, as a rule, guidelines on combination treatments have been based on expert consensus, as are ours.^{6,16,18,51,53,54} Compared to these sources, we have used fairly stringent consensus criteria. It has been acknowledged that expert advice may provide valuable guidance for a multi-modal approach to aesthetic treatment.⁵⁵

Parts of the available guidelines are focused on specific subpopulations, according to patients' ethnic origin, gender, or age^{6,18,19,53,54,56} as the achievement of optimal outcomes results from a patient-centred treatment plan

Table 4 Recently Published Consensus Guidelines on Combination Rejuvenation Treatments of the Face and Neck

that accounts for facial morphotype as well as personal and cultural aesthetic ideals.^{18,19} Indeed, facial morphology and age-related changes differ across ethnic groups,⁵⁴ which result in distinct treatment goals and priorities or components of combination treatments.^{6,18} However, the loss of volume occurs in all ethnicities, explaining the reason for volumisation always being a crucial step in rejuvenation treatment.¹⁹ The qualitative and quantitative differences in treatment are limited for early intervention/enhancement and restoration, most combination strategies being similar or slightly different in Asian and Caucasian patients.⁵³ In addition, our board-convened members from diverse geographic areas and cultural background ideals,

and the proposed protocols account for the main variations of ethnic aesthetic problems and ideals. However, our guidelines always need adaptation to specific contexts and individual needs.

Conclusion

These new practice guidelines will probably prove helpful for practitioners by advising the optimal management strategy in the multimodal rejuvenation treatment of different face areas when combining the PCL collagen stimulator, the PLLA/PLGA suspension sutures, and the cross-linked HA, whether associated or not with other frequently used MIPs. Individual treatment plans should

always be adapted according to the physician's individual competence and the patient's preferences and needs.

Clinical, Cosmetic and Investigational Dermatology

Dovepress

Publish your work in this journal

Clinical, Cosmetic and Investigational Dermatology is an international, peer-reviewed, open access, online journal that focuses on the latest clinical and experimental research in all aspects of skin disease and cosmetic interventions. This journal is indexed on CAS.

The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/clinical-cosmetic-and-investigational-dermatology-journal>
