Abstract: While the potential impact of magnetic nanoparticles (MNPs) has been widely explored in almost all medical fields, including cardiology, one question remains; that is whether MNPs interfere with cardiac physiological processes such as the expression and function of ion channels, especially in vivo. KCNQ$_1$ channels are richly expressed in cardiac myocytes and are critical to the repolarization of cardiac myocytes. In this study, we evaluated the effects of Fe$_3$O$_4$-magnetic nanoparticles (MNPs-Fe$_3$O$_4$) on the expression of KCNQ$_1$ in cardiac muscle of mice at rest and at different times following a single bout of swimming (SBS). Firstly, we demonstrated that the expression levels of KCNQ$_1$ channels are significantly up-regulated in mice following a SBS by means of reverse transcription polymerase chain reaction (RT-PCR) and western-blot. After treating mice with normal saline or pure MNPs-Fe$_3$O$_4$ separately, we studied the potential effect of MNPs-Fe$_3$O$_4$ on the expression profile of KCNQ$_1$ in mouse cardiac muscle following a SBS. A SBS increased the transcription of KCNQ$_1$ at 3 hours post exercise (3PE) 164% ± 24% and at 12 hours post exercise (12PE) by 159% ± 23% (P < 0.05), and up-regulated KCNQ$_1$ protein 161% ± 27% at 12PE (P < 0.05) in saline mice. In MNPs-Fe$_3$O$_4$ mice, KCNQ$_1$ mRNA increased by 151% ± 14% and 147% ± 12% at 3 and 12 PE, respectively (P < 0.05). Meanwhile, an increase of 152% ± 14% in KCNQ$_1$ protein was also detected at 12PE. These results indicated that the administration of MNPs-Fe$_3$O$_4$ did not cause any apparent effects on the expression profile of KCNQ$_1$ in rested or exercised mice cardiac muscle. Our studies suggest a novel path of KCNQ$_1$ current adaptations in the heart during physical exercise and in addition provide some useful information for the biomedical application of MNPs which are imperative to advance nanomedicine.

Keywords: KCNQ$_1$, cardiac muscle, magnetic nanoparticles of Fe$_3$O$_4$

Introduction

Nanotechnology is at the leading edge of the rapidly developing, new therapeutic and diagnostic concepts in all areas of medicine.¹ Nanoscale materials are a broadly defined set of substances in which at least one critical dimension is less than 100 nanometers.² The unique ability of magnetic nanoparticles (MNPs) to be functionalized with bioactive agents and respond to a magnetic field has made them a useful tool for: magnetic resonance imaging; targeted drug and gene delivery; magnetic hyperthermia cancer therapy; tissue engineering, and cell tracking to name a few.³⁻⁶ Our previous study also proposed that daunorubicin-loaded magnetic nanoparticles of Fe$_3$O$_4$ (MNPs-Fe$_3$O$_4$) can overcome the multi-drug resistance of certain carcinoma cells, both in vitro and in vivo.⁷⁻⁸ While mounting evidence suggests that MNPs have numerous advanced applications and the benefits of nanotechnology are widely publicized, in vivo data on
the potential effects of pure MNPs on mammals are limited. An understanding of the interface between the MNPs and specific organs, for to their application and safety, are imperative to advance nanomedicine. Although there are several reports showing that MNPs may be accumulated in tissues when administered at clinically relevant concentrations, via relevant routes, show unremarkable histological changes in vital organs, suggesting their safety in the respective formulations to some degree. However information on the physiological function of vital organs after the administration of MNPs is rarely reported.

The heart is a rhythmic electro-mechanical pump, the functioning of which depends on action potential (AP) generation and propagation, followed by relaxation and a period of refractoriness until the next impulse is generated. Cardiac repolarization is a key cellular function. Disruption of cardiac repolarization leads to potentially lethal ventricular tachyarrhythmias. Delayed rectifier K⁺ current (I_{Ks}) is the major outward current involved in ventricular repolarization. Two components of I_{Ks}, the rapid voltage-gated potassium current, I_{Kr}, and slow voltage-gated potassium current, I_{Ks}, have been identified. A prolongation of APs under a variety of conditions would favor the activation of I_{Ks} so as to prevent excessive repolarization delay, causing early depolarization. The pore-forming subunit of the voltage-dependent K⁺ channel underlying I_{Ks} is KCNQ_1.

The KCNQ_1 is a 6-transmembrane protein that can either form a functional homeric potassium channel or coassemble with the single transmembrane domain protein encoded by the KCNE family of genes to form a heteromeric channel, the slow voltage-gated potassium channel (I_{Ks} channel). Mutations in the cardiac KCNQ_1 have been linked to the long QT syndrome (LQTS), which predisposes patients to arrhythmia during exercise and emotional stress, conditions that involve high levels of sympathetic nervous system activity.

Stimulation of the sympathetic nervous system (SNS) in response to exercise or emotional stress results in a rapid and dramatic increase in heart rate. To ensure adequate diastolic filling time between beats, the ventricular action potential duration (APD) exhibits a concomitant shortening at the cellular level, which results in a reduction in the corresponding QT interval of the electrocardiography (ECG). The enhancement of slow voltage-gated potassium current I_{Ks} plays a major role in this process. Although some reports show that the activity of I_{Ks} channel can be upregulated in the face of elevated SNS activity. It is currently unknown whether the remodeling of I_{Ks} channel expression may be induced by the stimulation of exercise.

In this study, we investigated the expression profile of KCNQ_1 in mouse cardiac muscle following a single bout of swimming (SBS). In order to assess the potential effects of pure MNPs on mammal heart, we also treated mice with normal saline or MNPs-Fe₃O₄ separately and then examined the effects of MNPs-Fe₃O₄ on the expression of KCNQ_1 in exercised and non-exercised mouse heart. MNPs-Fe₃O₄ have not been found to downregulate the apoptosis-associated genes in certain carcinoma cells.

**Material and methods**

**Preparation of MNPs-Fe₃O₄**

MNPs-Fe₃O₄ were produced by electrochemical deposition under oxidizing conditions in a 0.1 mol/L tetraheptylammonium-2-propanol solution, in which the magnetization and particle size of MNPs-Fe₃O₄ were found to be 25.6 × 10⁻⁷ emu/mg and 30 nm, respectively. The deposited clusters were capped with tetraheptylammonium-2-propanol, which acts as a stabilizer of the colloidal nanocrystallites. Before being applied in this experiment, the magnetized nanoparticles of Fe₃O₄ were well distributed in 0.9% NaCl solution by using ultrasound treatment in order to obtain colloidal suspension of MNPs-Fe₃O₄.

**Animals**

Four-week-old, male BALB/c-nu/nu mice were purchased from Beijing National Center for Laboratory Animals, the Chinese Academy of Medical Sciences prior to the beginning of our experiments. Both food and water were provided *ad libitum*.

**Exercise protocols**

Forty-two mice were randomly assigned to either the non-exercised control group (n = 6) or exercise groups (n = 36). Thirty-six mice were placed into plastic cylinders (23 cm tall × 14 cm diameter) containing water (22–24°C) filled to a depth of 15 cm for a 30-minute swim. Non-exercised controls were kept in their home cage for the duration of the test. Mice completing the exercise were euthanized via cervical dislocation immediately or at 1, 3, 6, 12, or 24 hour after exercise. Until euthanasia, food and water were provided *ad libitum*. The ventricles were quickly dissected from each mouse, frozen in liquid nitrogen, and stored at −80°C until assayed.

For the study of the MNPs-Fe₃O₄, 48 mice were assigned randomly into 2 groups (n = 24) and treated with normal saline 0.2 mL or MNPs-Fe₃O₄ (0.2 mL, 0.58 mg/kg) every other day for 14 day by vena caudalis injection, respectively.
Mice treated with normal saline or MNPs-Fe$_3$O$_4$ were then randomly assigned to either non-exercised control group (n = 6) or the exercise groups (n = 18) respectively. Mice were exposed to a 30-minute swim 1 day after the last injection. All experiments were conducted at approximately the same time of day. After completing the exercise the mice were euthanized via cervical dislocation at 3, 12, or 24 hour after exercise (Table 1). Until euthanasia, food and water were provided ad libitum.

**Semiquantitative polymerase chain reaction (PCR)**

The dissected left ventricles were crushed into a fine powder using a mortar and pestle. Total RNA was extracted using TRIzol® (Invitrogen, Carlsbad, CA, USA), and RNA concentrations were determined spectrophotometrically at 260 nm. RNA was treated with DNase to eliminate potential genomic DNA contamination, and reverse transcription and polymerase chain reaction (PCR) were performed with 1 µg of total RNA using ReverTraAce® a (Toyobo, Osaka, Japan). cDNAs were amplified by PCR in a Bio-Rad Mycycler thermal cycler. PCR was undertaken with triplicate samples prepared from each animal, in each group. Each reaction contained 500 ng cDNA. The PCR primers used were as: KCNQ1 (525bp) forward primer, 5’-CACCTCAGGTCCTCAGTGCAACT-3’; reverse, 5’-TTGCGGATCCTTGTGCGGC-3’; β-actin (360bp) forward primer, 5’-TTGGCAGCTCCTGTTGGC-3’; reverse, 5’-GCCTCGGTA AGGCAGCAGG-3’. Cycle times used for each primer pair were within the linear increase in PCR product. PCR products were separated and visualized in 1.5% agarose gels with ethidium bromide. Band intensities of KCNQ1 were quantitated using ImageQuant™ software and normalized to β-actin.

**Western blot analysis**

Left ventricular tissue was homogenized with 500 µL lysis buffer (100 mM/L Tris [pH 6.8], 4% sodium dodecyl sulfate [SDS], 20% glycerol) containing the protease inhibitor phenylmethanesulfonyl fluoride 0.1 mM/L. We separated 50 µg of proteins on SDS–polyacrylamide gel electrophoresis 10%. Proteins were transferred to nitrocellulose membrane (Bio-Rad Laboratories, Hercules, CA, USA) blocked with 5% dry milk and exposed to rabbit polyclonal antibody anti-KCNQ1 (H-130: sc-20816, [Santa Cruz Biotechnology, Santa Cruz, CA USA]; dilution 1:2,000 in bovine serum albumin (BSA) 5%), rabbit polyclonal antibody anti-β-actin (ab8227, [Abcam, Cambridge, MA, USA]; dilution 1:5,000 in BSA 5%). Immunodetection was accomplished using goat anti-rabbit IgG (Sigma-Aldrich, St. Louis, MO, USA) secondary antibodies (dilution 1:4,000 in BSA 5%), and a chemiluminescence kit (Amersham Biosciences, Little Chalfont, Buckinghamshire, UK). Band intensities were analyzed by densitometry. Band intensities of KCNQ1 were normalized to β-actin.

**Statistical analysis**

All data are expressed as means ± SE. The effect of swimming on expression of KCNQ1 was analyzed using one-way analysis of variance (ANOVA). Two-way ANOVA was used for Fe$_3$O$_4$ administration studies.

**Results**

**Acute exercise enhanced KCNQ1 mRNA and protein expression in mouse cardiac muscle**

Compared to mice in the non-exercise control group (basal), a 30-minute single bout of swimming enhanced the transcription of KCNQ1 mRNA in the heart at 3, 6, and 12 hour post exercise (PE) (P < 0.05, Figure 1). The expression level of KCNQ1 mRNA returned to approximately control levels within 24-PE.

Expression of KCNQ1 protein significantly increased with exercise in mice at 12PE compared with the non-exercised basal animals (P < 0.05, Figure 2), and the amount of KCNQ1 protein decreased nearly to base level at 24PE.

**Effect of Fe$_3$O$_4$ magnetic nanoparticles on acute exercise enhanced KCNQ1 expression in mouse cardiac muscle**

Over the course of the 14-day treatment with normal saline or MNPs-Fe$_3$O$_4$, mice showed no significant health problems. Drug administration also did not appear to affect exercise performance.

The amount of KCNQ1 mRNA increased significantly at 3PE and 12PE compared to basal animals (P < 0.05) both in

saline and MNPs-Fe₃O₄ group (Figure 3, Table 2). Expression of KCNQ₁ protein also increased significantly at 12PE when compared to basal animals (P < 0.05) both in saline and MNPs-Fe₃O₄ group (Figure 4, Table 2).

No significant differences were found in KCNQ₁ expression profile between MNPs-Fe₃O₄ mice and control saline mice at rest or post exercise (Figures 3 and 4, Table 2).

**Discussion**

The present study examined firstly the effect of a single bout of swimming on the expression of KCNQ₁ in mouse cardiac muscle. Our data shows a 30-minute bout of swimming enhanced KCNQ₁ expression at 3PE and 12PE. Administrations of MNPs-Fe₃O₄ had no significant influence or enhancement effect of acute exercise on KCNQ₁ expression in mouse cardiac muscle.

Cardiac APs are driven by ionic currents flowing through specific channels and exchangers across cardiomyocyte membranes. Voltage-gated K⁺ currents play a major role in repolarization of APs. KCNQ₁ is a 6-transmembrane domain protein that can form the slow voltage-gated potassium channel (I_Ks channel) constituting the slowly activating potassium current I_Ks. There is a growing number of studies that suggest that the I_Ks is important for AP repolarization and APD adaptation to changes in heart rate.¹⁶,¹⁷ The importance of the KCNQ₁ channel at fast heart rates is especially evident from the fact that exercise or emotional stress conditions, which involve high levels of beta-adrenergic stimulation, trigger arrhythmias in more than 80% of patients with the long QT syndrome (LQTS) which arise from mutations in KCNQ₁.²⁰ The activation of β-adrenergic receptors can regulate select ion channel proteins via cAMP-dependent protein kinase A (PKA) or by direct binding of cAMP to channel subunits.
One key substrate for PKA-dependent phosphorylation in the regulation of the cardiac action potentials is the $I_{Ks}$ channel.\textsuperscript{21} Augmentation of $I_{Ks}$ current by $\beta$-adrenergic stimulation plays an important role in mediating cardiac electrophysiological response during exercise and emotional stress.\textsuperscript{16} Despite the elucidation of the macromolecular signaling complex and striking clinical data, the possibility that exercise might induce remodeling of $I_{Ks}$ channel expression has not been tested.

Our present results show that the transcription and expression of KCNQ$_1$ are increased following a 30-minute swimming. These data indicate the remodeling of KCNQ$_1$ expression that might partially compensate for the shortening of cardiac action potential duration; which results in a reduction in the corresponding QT interval of the electrocardiogram.\textsuperscript{22}

The potential benefits of nanotechnology in medicine are inevitable, owing to refined, highly targeted: blood-brain

barrier-crossing drug delivery and imaging platforms; unique transfection; labeling and bioseparation, together with analytical and tissue engineering approaches. The versatility of MNPs is due to their capability of responding to an external magnetic field and can be functionized with bioactive agents at the same time and/or differentially. For successful application of MNPs, it is essential to understand the real effect of the pure MNPs on vital organs and cells.

MNPs size, charge, surface chemistry and route of delivery each influence their effective time and biodistribution patterns in the body. Large (>200 nm) particles are usually sequestered by the spleen via mechanical filtration followed by phagocytosis, whereas smaller (<10 nm) particles are rapidly removed through extravasation and renal clearance, with particles 10–100 nm believed to be optimal for intravenous administration. In this study, pure MNPs-Fe3O4 (30 nm) were used for the evaluation of their potential effect on the protein expression in the heart as well as exercise ability. The results showed that pure MNPs did not cause any apparent effects on swimming behavior nor in the KCNQ1 expression profile before or after exercise.

Conclusion
In conclusion, our results indicate a novel path of Ios current adaptations in the heart during physical exercise. Compared with mice in the non-exercise control group expression of KCNQ1 in the heart were significantly increased following exercise. Therefore, not only the increased activity but also the enhanced expression of KCNQ1 channel might contribute to current MNP-Fe3O4 adaptations in the face of elevated sympathetic nervous system activity. Further study shows that the administration of MNPs-Fe3O4 has no significant influence on the expression profile of KCNQ1 in rested or in exercised mice cardiac muscle. These data might provide some useful information required to improve MNP formulations and biomedical applications which are imperative to advance nanomedicine.
