Background: Pancreatic cancer is one of the most malignant tumors, and gemcitabine has been considered as the standard treatment and been widely utilized as a first-line drug for advanced pancreatic cancer, but gemcitabine-resistance always occurs after a short period of treatment.

Methods: Two pancreatic cancer cell lines Panc-1 and MIA-PaCa-2 were used as the study subject and their gemcitabine-resistant cells were established. Both drug-resistant cells were divided into four groups: blank, emodin, gemcitabine, and emodin+gemcitabine. Cell viability was detected by MTT assay. Flow cytometry was performed to detect cell apoptosis rate and P-gp function. Quantitative real-time polymerase chain reaction and Western blotting were used to detect *Survivin*, *XIAP*, *Caspase-9/3*, *NF- κ B p65*, *IKK β* and *I κ B- α* mRNA/protein expressions, respectively. Electrophoretic mobility shift assay (EMSA) was performed to detect *NF- κ B* binding activity. Rhodamine 123 efflux assay was used to detect P-gp function.

Results: Emodin could inhibit cell activity in all cell lines. Both emodin and gemcitabine can significantly increase the apoptosis rate, and the combination of the two drugs can further significantly increase the apoptosis rate in normal pancreatic cancer cell lines. In both drug-resistant pancreatic cancer cell lines, it can be observed that although gemcitabine can increase the apoptosis rate, the effect of promoting apoptosis is significantly lower than that of emodin; the drug combination can still significantly increase the apoptosis rate on the basis of emodin alone. Emodin can significantly reduce the mRNA and protein expression levels of *Survivin*, *XIAP*, *NF- κ B*, and *IKK β* , and significantly increase the mRNA and protein expression levels of *Caspase-3/9* and *I κ B- α* . Emodin significantly reduced *NF- κ B* activity and emodin significantly promoted P-gp fluorescence intensity from Rhodamine 123 efflux assay.

Conclusion: Emodin inhibits the expression of *IKK β* , thereby inhibiting the expression and activity of downstream *NF- κ B*, and inhibits P-gp function at the same time, ultimately achieving the purpose of reversing the drug-resistance of pancreatic cancer cell lines.

Keywords: emodin, pancreatic cancer, gemcitabine, NF- κ B, I κ B- α

Introduction

Pancreatic cancer is one of the most malignant tumors, and East Asian countries, especially the People's Republic of China, have been the regions with the highest incidence of pancreatic cancer. According to statistics, in 2015, there were 48,960 new pancreatic cancer patients in the People's Republic of China, and the number of

deaths was as high as 40,560.¹ Pancreatic cancer has a poor prognosis, with a median survival time of less than 6 months and a 5-year survival rate of only 5%.^{2,3} Although in recent years, the level of pancreatic cancer-related surgery has greatly improved, 80% of patients with pancreatic cancer are diagnosed at an advanced stage that cannot be treated surgically, due to the lack of early clinical symptoms of pancreatic cancer and the high metastatic potential of pancreatic cancer. Most of them are accompanied by distant metastases, so less than 20% of patients are suitable for surgical resection.^{4,5} Chemotherapy is another important method to treat advanced pancreatic cancer and prolong the survival of patients.⁶ In the last decade, gemcitabine has been the first-line chemotherapy drug of choice for clinical treatment of advanced pancreatic cancer,⁷ two combination regimens for metastatic pancreatic cancer have turned out to be gold standards in recent years: 5-fluorouracil (5-FU)/leucovorin with irinotecan and oxaliplatin (FOLFIRINOX), and gemcitabine with nab-paclitaxel since 2011.⁸ Gemcitabine has become a blockbuster drug for the treatment of advanced pancreatic cancer since it was launched in 1996.⁹

Unfortunately, patients with pancreatic cancer develop resistance to gemcitabine after a few weeks of administration. The emergence of this acquired resistance has greatly limited the clinical efficacy of gemcitabine.¹⁰ More and more evidence indicates that *NF- κ B* may be the most important regulatory molecule among them, not only because of the high expression of *NF- κ B* in most gemcitabine-resistant cell lines, but also because *NF- κ B*, as a widely acting transcription factor, also plays an important transcriptional regulatory role on gemcitabine resistance-related proteins including *ENT*, *HIF1- α* .^{11–13}

As the dominant subunit of regulatory kinases in the classic *NF- κ B* signaling pathway, *IKK β* plays a huge role in regulating cell proliferation, apoptosis, and metastasis. Therefore, the *IKK β /NF- κ B* signaling pathway has been one of the most popular anti-tumor targets, and its over-activation has been found in almost all solid tumor cells.^{14,15}

In summary, *IKK β /NF- κ B* signaling pathway inhibitors have great potential in reversing gemcitabine resistance and are expected to become potential drugs to overcome the clinical problem of gemcitabine resistance. Unfortunately, the related research in this area has not yet attracted enough attention. In addition, currently known inhibitors of *IKK β /NF- κ B* signaling pathways, such as BMS-345,541, ML-120B, TPCA-1, etc., although they have good inhibitory activity, are also

accompanied by strong cytotoxic effects.^{16–18} Curcumin and its analogs EF24 and EF31 are also toxic, and there are huge defects in drug metabolism.^{19–21} Therefore, finding a new type of *IKK β /NF- κ B* inhibitor with high efficiency and low toxicity, and exploring if it can reverse the resistance of gemcitabine has become our main research goal.

Our previous research screened a large number of active monomers from natural products, and successfully found that the natural product emodin had good anti-pancreatic cancer activity. Numerous papers have also reported that emodin had a significant inhibitory effect on a variety of solid tumors including gastric, breast, lung, liver, and pancreatic cancer.^{22–24} Unfortunately, the molecular target of emodin has not been confirmed, which greatly limits the clinical application prospect of using emodin as an antitumor drug.

In previous studies, we found that emodin showed synergistic antitumor effects with gemcitabine in vivo and in vitro. However, the specific effect and detailed mechanism of its resistance reversal need to be further studied. Based on the results reported in the existing literature and our preliminary basis, we propose the hypothesis that the reversal effect of emodin on gemcitabine resistance in pancreatic cancer cells is exerted by inhibiting *IKK β* , then we will further verify the correlation between abnormal activation of *IKK β* and gemcitabine resistance in pancreatic cancer.

Materials and Methods

Reagents and Drugs

Emodin (Sigma, USA) was dissolved in DMSO (dimethylsulfoxide), the concentration of the solution was 0.2 mmol/L, and it was stored at -20°C . Gemcitabine (Ely Lilly, Germany) was dissolved in sterile saline, the concentration of the solution was 50 g/L. FBS (fetal bovine serum) and DMEM were purchased from Gibco (USA).

Cell Culture

Panc-1 and MIA-PaCa-2 (human pancreatic cancer cell lines) were obtained from ATCC (USA). Cells were cultured in RPMI-1640 purchased from Gibco, then they were supplemented with 10% FBS (Gibco, USA), and were kept in 5% CO_2 + 37°C incubator.

Resistant Cell Lines Panc-1/Gem and MIA-PaCa-2/Gem Establishment

Gemcitabine-resistant cell lines Panc-1/Gem and MIA-PaCa-2/Gem were derived from the human pancreatic cancer cell lines Panc-1 and MIA-PaCa-2 by exposing

the cells to intermittently increasing concentrations of gemcitabine. After a week, cell death was observed, therefore, median lethal dose (LD80) was chosen as the initial concentration to cultivate the resistant cell line for 72 hours. Cells were passaged twice and cultivated with a double LD80 concentration of gemcitabine when cells entered the logarithmic growth phase. The process lasted 10 months, there were a total of nine concentration gradients.

Cell Grouping

Both cell lines were divided into four groups, namely the blank group, the emodin group, the gemcitabine group, and the emodin + gemcitabine group. The blank group was treated with normal saline, the emodin group was treated with 40 μ M concentration of emodin, the gemcitabine group was treated with 20 μ M concentration of gemcitabine, and the emodin + gemcitabine group was the combination of two drugs.

Inhibition Effect of Emodin at Different Concentrations on Cell Proliferation

Cells in logarithmic phase were cultured in 96-well plates (4×10^3 /well) in an incubator with 5% CO₂ at 37°C overnight. Emodin with a concentration of 10, 20, 40, 80 and 160 μ M was administered to cells for 72 hours ($n = 6$). In addition, a group of series was set: emodin of 40 μ M alone, gemcitabine of 20 μ M alone, emodin + gemcitabine (combination) and a control group (blank) with only normal saline ($n = 6$). incubation was continued at 37°C for 72 hours, then 20 μ L MTT solution (5g/L) was added to each well, and followed by incubating in a 37°C 5% CO₂ incubator for 4 hours. Next 200 μ L of standard concentration of DMSO was added to each well, mixed by shaking for 15 minutes, and then the absorbance value was measured with a microplate reader at 490 nm wavelength. Cell viability = Absorbance of test group/Absorbance of Control group $\times 100\%$.

Flow Cytometry

The cells in each group were counted after resuspending in medium. About 1×10^6 cells were moved into a centrifuge tube and centrifuged at 1000 r/min for 5 minutes before discarding the supernatant, adding 1 mL of PBS solution, and gently shaking the tubes to suspend the cells. The cells were then centrifuged at 1000r/min for 5 minutes before discarding the supernatant and repeating 2 times. Next, 500 μ L of binding

buffer was added to the cells, and gently shaken to suspend the cells, before adding 5 μ L of Annexin V-FITC and mixing gently. The cells were kept at room temperature for 15 minutes in the dark, after which 300 μ L of binding buffer and 10 μ L of PI were added and mixed gently. After incubating the cells at room temperature in the dark for 5 minutes, the data was obtained through Cell Quest software.

Western Blot

The cells in each group were extracted according to the instructions of the protein extraction kit (Beyotime, the People's Republic of China), and the total protein was measured using the BCA kit. The extracted protein samples were electrophoresed in SDS-PAGE, and transferred to nitrocellulose membrane, then samples were closed with 5% skimmed milk for 2 hours. Add the appropriate concentration of primary antibody anti-survivin, anti-XIAP, anti-Caspase-9, anti-Caspase-3, anti- IKK β , anti-NF- κ B p65, anti- I κ B- α primary antibodies (all purchased from Abcam) overnight at 4°C, the internal reference was β -actin. After washing the membrane, the secondary antibody was incubated for 2 hours. After color exposure, protein bands were obtained. Image Lab software was used to analyze the gray value of the protein bands and the relative expression of the protein. The experiment was repeated 3 times.

Quantitative Real-Time PCR

Total RNA was extracted using TRIzol reagent (Invitrogen, USA). Applied Biosystems 7300 Fast Real-Time PCR system was used. Primers were specifically designed by Applied Biosystems Primer Express 3.0 (Thermo Fisher Scientific, USA). Specific primers were fixed using the BLAST program. Each 20 μ L reaction contained 1 \times SYBR[®] Premix Ex Taq[™] II, 10 μ M forward and reverse primers, 0.4 μ L ROX reference dye and 2 μ L cDNA. The primer sequences are provided in Table 1. ABI 7300 sequencer reaction conditions are: 94°C 5 minutes, 94°C 40 seconds \times 40 cycles, 60°C 40 seconds. The relative quantification (RQ) of target gene expression is calculated by the $2^{-\Delta\Delta CT}$ method. GAPDH was the internal reference. The PCR reaction was repeated 3 times for each sample.

Electrophoretic Mobility Shift Assay (EMSA)

The DNA probes used in this experiment were amplified and recovered by PCR technology. The amplification primer was introduced with 5'biotin label during synthesis for

subsequent detection. The operation of the EMSA test was based on the instructions of the LightShift® Chemiluminescent EMSA Kit (Thermo Fisher Scientific). The protein, probe and reaction buffer were completed in a 20 µL reaction system. During the test, the reaction system was incubated at room temperature for 20 minutes. Then staining agent was added to it and it was placed in 6.5% non-denaturing gel, and run in 0.5×TBE buffer for 1 hour. After electrophoresis was completed, nylon membrane was used for transfer, cross-linking, and color development. The chemiluminescence imager was used to observe the binding of NF-κB protein to the target gene probe.

Rhodamine 123 Efflux Assay of P-gp Function in Panc-1/Gem and MIA-PaCa-2/Gem Cells (Flow Cytometry)

Rhodamine 123 staining solution with 10 µL/mL (Changchun Keygen Biological Products Co., Ltd., the People's Republic of China) was added to the culture media, then cells were cultured in 5% CO₂ at 37°C for 30 minutes and then centrifuged at 2000 r/min for 5 minutes and washed twice, resuspended and incubated for 2 hours. Finally, the cells were centrifuged twice, washed twice with PBS and the fluorescence intensity was measured by flow cytometry at 488/530 nm.

Synergy Assessment

Growth inhibition following combinations of gemcitabine with and without emodin was performed (emodin at 10, 20, 40, 80 and 160 µM, gemcitabine 20 µM) in Panc-1 and MIA-PaCa-2 cell lines. After 72 hours, cell viability was quantified using CellTiter-Glo Luminescent Cell Viability Assay (Promega). Growth was normalized to wells treated with DMSO vehicle (100% viability) and bortezomib (0% viability). Synergy was scored using Bliss independence modelling as described below.

Statistical Analysis

Data analysis were performed by SPSS 21.0 software. Data were expressed as mean ± standard deviation. The *t*-test was performed for comparisons between the two groups. One-way analysis of variance was applied for comparisons among multiple groups. Statistical significance was assumed as *P* < 0.05.

Bliss independence between the drug responses to combinations of the two drugs equalled the sum of the two fractional responses of individual drugs minus their product, where (Fa + Fb) – (Fa × Fb). ΔBliss is zero for a given dose combination when there is no overall synergy or antagonism, while negative ΔBliss values indicate synergy at that combination. Overall synergy score for a drug combination was calculated by ΣΔBliss.

Results

Emodin Inhibits Pancreatic Cancer Cell Growth

Stable gemcitabine-resistant cell lines Panc-1/Gem and MIA-PaCa-2/Gem were generated from their parental cell lines Panc-1 and MIA-PaCa-2 by exposing them to intermittently increasing concentrations of gemcitabine for 10 months. Their IC₅₀ for gemcitabine increased significantly compared to their parental cell lines (Panc-1: 0.201 µM vs Panc-1/Gem: 359.9 µM; MIA-PaCa-2: 0.087 µM vs MIA-PaCa-2/Gem: 570.6 µM, [Figure 1A](#) and [B](#)). Different concentrations of emodin were applied to Panc-1, Panc-1/Gem, MIA-PaCa-2, and MIA-PaCa-2/Gem cell lines. The results are shown in [Figure 1](#). Emodin could inhibit cell viability in all cell lines, and the higher the dose, the stronger the inhibitory effect ([Figure 1C](#) and [D](#)). Emodin's inhibitory effect was statistically significant starting from a concentration of 40 µM, *P* < 0.05, so our subsequent experiments were carried out at a concentration of 40 µM. Furthermore, drug effect was detected on gemcitabine-resistant cell lines and their parental cell lines, results ([Figure 1E](#)) showed that emodin alone could significantly reduce cell viability compared to the blank group after 72 hours of drug exposure, *P* < 0.05, while gemcitabine had no significant effect on gemcitabine-resistant cells, *P* > 0.05. Growth inhibition over 72 hours was quantified after gemcitabine alone and in combination with emodin at different concentrations by CellTiter-Glo, the ΔBliss analysis was –0.647, demonstrating that emodin had a synergic effect with gemcitabine.

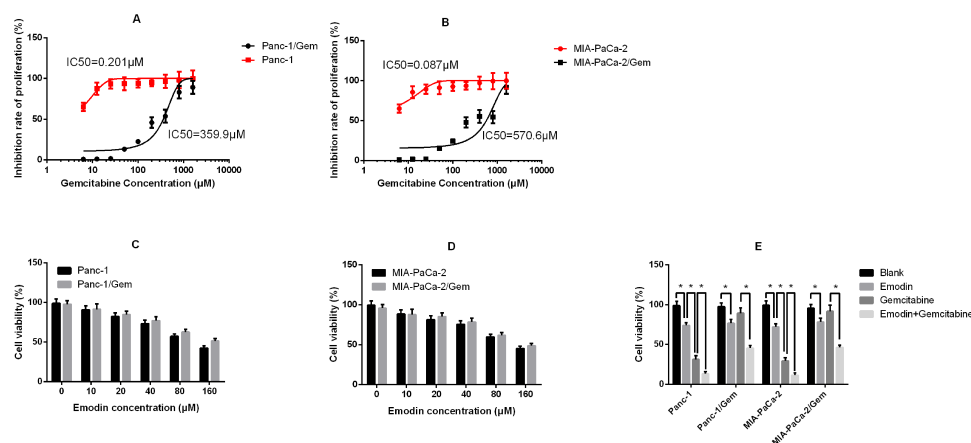

Figure 1 (A) Inhibition rate of proliferation of Panc-1 (parental cell line) and Panc-1/Gem (gemcitabine-resistant cell line); (B) Inhibition rate of proliferation of MIA-PaCa-2 (parental cell line) and MIA-PaCa-2/Gem (gemcitabine-resistant cell line). (C) Cell viability of Panc-1 and Panc-1/Gem cells after 72 hours of emodin application at different concentrations detected by MTT assay. (D) Cell viability of MIA-PaCa-2 and MIA-PaCa-2/Gem cells after 72 hours of emodin application at different concentrations detected by MTT assay. (E) Cell viability of all cell lines after 72 hours of treatment from all groups (emodin 40 μ M, gemcitabine 20 μ M). **P* < 0.05.

Emodin Promotes Cell Apoptosis of Pancreatic Cancer Cell Lines

It can be observed in two normal pancreatic cancer cell lines (Figure 2) that: compared to the blank group, both emodin and gemcitabine can significantly increase the

apoptosis rate, and the combination of the two drugs can further significantly increase the apoptosis rate after 72 hours of drug exposure, all *P* < 0.05. There was no statistically significant difference in the apoptosis rate between emodin and gemcitabine groups, *P* > 0.05. On the other

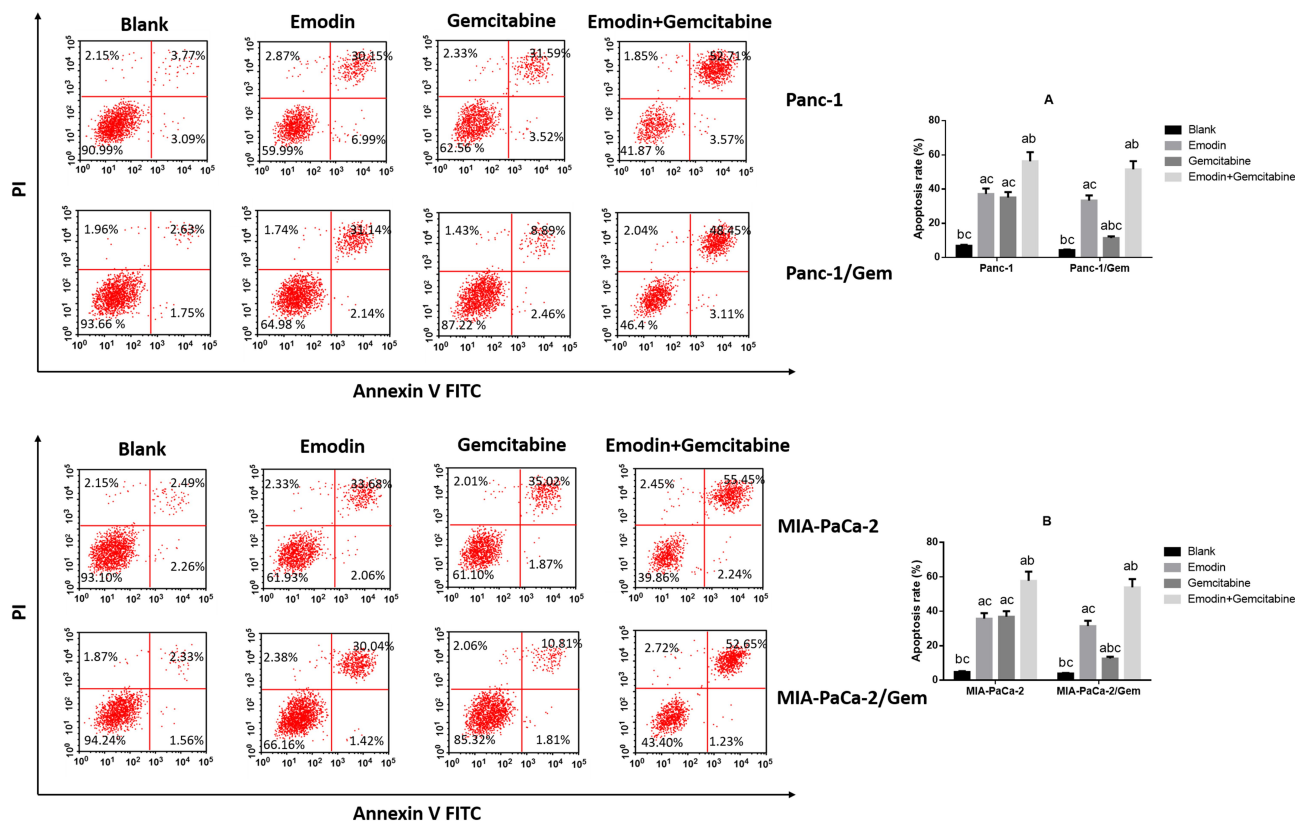

Figure 2 Cell apoptosis was detected by Flow cytometry. (A) Emodin's effect on cell apoptosis of Panc-1 and Panc-1/Gem cells. (B) Emodin's effect on cell apoptosis of MIA-PaCa-2 and MIA-PaCa-2/Gem cells. ^a*P* < 0.05 compared to the blank group, ^b*P* < 0.05 compared to emodin group, ^c*P* < 0.05 compared to the gemcitabine group.

hand, in both drug-resistant pancreatic cancer cell lines, it can be observed that although gemcitabine can increase the apoptosis rate, the effect of promoting apoptosis is significantly lower than that of emodin, $P < 0.05$. The drug combination can still significantly increase the apoptosis rate on the basis of emodin alone, $P < 0.05$.

Emodin Reduces NF- κ B and IKK β Expressions

The qRT-PCR result showed that NF- κ B p65 and IKK β mRNA expressions were significantly up-regulated in parental cell lines (Panc-1 and MIA-PaCa-2), while I κ B- α mRNA expression was significantly down-regulated (Supplementary figure 2E and F), suggesting that NF- κ B pathway was more active in gemcitabine-resistant cell lines. It was observed in two drug-resistant pancreatic cancer cell lines (Figure 3 and Supplementary figure 2) that after 72 hours of drug exposure, the use of gemcitabine did not significantly change the mRNA and protein expression levels of *survivin*, *XIAP*, NF- κ B, IKK β and I κ B- α , all $P > 0.05$, while emodin can significantly reduce the mRNA and protein expression levels of *survivin*, *XIAP*, NF- κ B and IKK β , and significantly increase the mRNA and protein expression levels of *caspase-3/9* and I κ B- α , all

$P < 0.05$; The combination of drugs can significantly expand this change on the basis of emodin alone: the mRNA and protein expression levels of *survivin*, *XIAP*, NF- κ B and IKK β were significantly reduced, and the mRNA and protein expression levels of *caspase-3/9* and I κ B- α were significantly increased, all $P < 0.05$. Meanwhile, the NF- κ B, IKK β and I κ B- α expressions in the parental cell lines shared a similar tendency (Supplementary figure 1A–D), showing that emodin can have an effect in both parental and drug-resistant cell lines.

Emodin Reduces NF- κ B Activity

NF- κ B DNA binding activity of nuclear extracts were detected by EMSA. As shown in Figure 4, in both Panc-1/Gem and MIA-PaCa-2/Gem cell lines, compared with the blank group, emodin significantly reduced NF- κ B activity, $P < 0.05$, while gemcitabine significantly increased NF- κ B activity. Additionally, emodin combined with gemcitabine could still significantly decrease NF- κ B DNA-binding activity on the basis of emodin alone, $P < 0.05$.

Emodin Reduces P-gp Function

P-glycoprotein (P-gp), also called ABCB1 (ATP-ABC subfamily B member 1) or MDR1 (for multiple drug resistance), plays an important role in development of drug

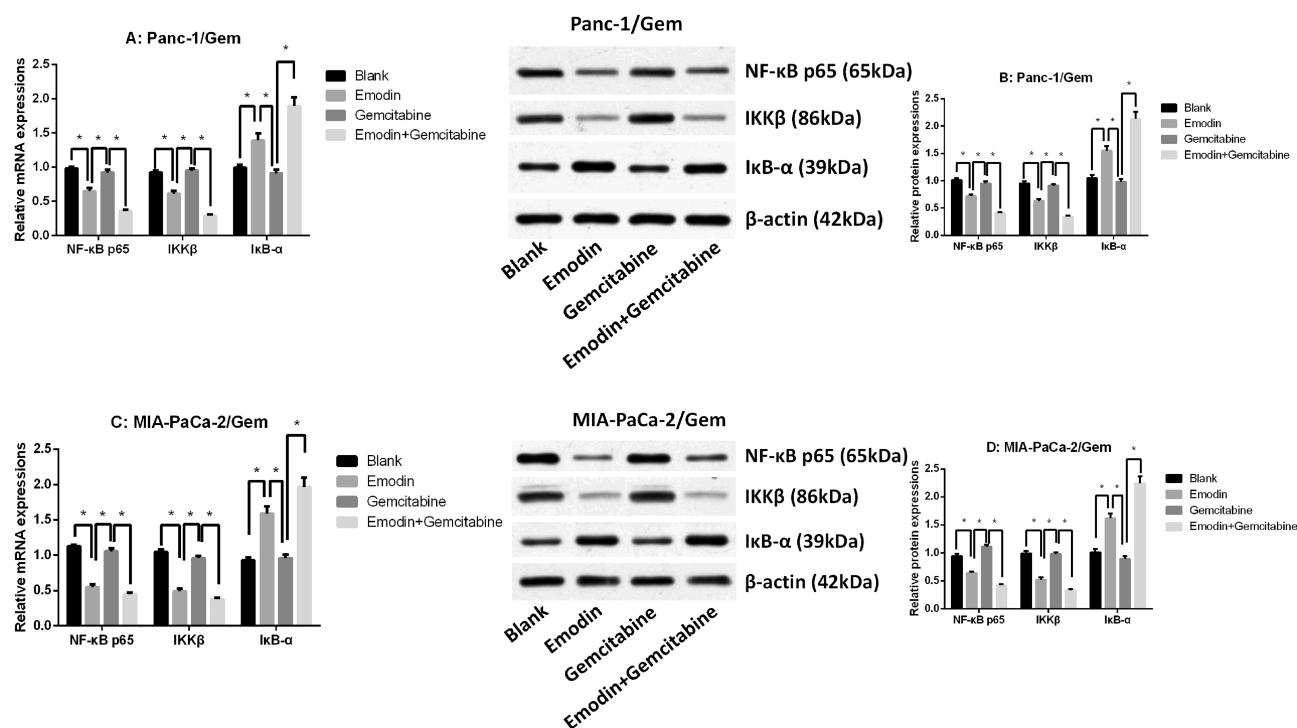

Figure 3 (A) mRNA expressions of NF- κ B p65, IKK β and I κ B- α of Panc-1/Gem cell. (B) mRNA expressions of NF- κ B p65, IKK β and I κ B- α of MIA-PaCa-2/Gem cell. (C) Protein expressions of NF- κ B p65, IKK β and I κ B- α of Panc-1/Gem cell. (D) Protein expressions of NF- κ B p65, IKK β and I κ B- α of MIA-PaCa-2/Gem cell. * $P < 0.05$.

Figure 4 (A) Emodin's effect on *NF-κB* and its downstream signaling protein expressions in Panc-1/Gem cell detected by Western Blot. **(B)** Emodin's effect on *NF-κB* and its downstream signaling protein expressions in MIA-PaCa-2/Gem cell detected by Western Blot. ^a $P < 0.05$ compared to the blank group, ^b $P < 0.05$ compared to the emodin group, ^c $P < 0.05$ compared to the gemcitabine group, ^d $P < 0.05$ compared to the emodin+gemcitabine group.

resistance. Rhodamine 123 (Rh123) is a fluorescent dye which locates in the mitochondria of cells. It is a substrate for P-glycoprotein (*P-gp*) and can, therefore, be used as a molecular probe in studies of the multidrug resistance (*MDR*) phenotype. Flow cytometry was used to measure rhodamine 123 efflux in drug-resistant pancreatic cancer cell lines. As shown in Figure 5, after 72 hours of drug exposure, in both Panc-1/Gem and MIA-PaCa-2/Gem cell lines, compared with the blank group, emodin significantly promoted fluorescence intensity, $P < 0.05$, while gemcitabine had no significant effect on it, $P > 0.05$. Emodin combined with gemcitabine could also significantly increase the fluorescence intensity, $P < 0.05$, but compared to emodin alone, the difference was not significant, $P > 0.05$.

Discussion

Resistance to anticancer drugs is the primary cause of the failure of chemotherapy for malignant tumors. It includes both intrinsic resistance and acquired resistance. Acquired resistance is the result of natural selection by anticancer drugs, it consists of a gradually developed resistance in an

originally sensitive cancer during anticancer drug therapy, and it occurs in almost half of all cancer patients.²⁵ Gemcitabine-resistant pancreatic cancer is one of the acquired resistances occurring in pancreatic cancer patients.

Emodin is a polyhydroxyanthraquinone compound extracted from the dried rhizomes and roots of *Polygonum cuspidatum* and rhizomes of *Rhubarb palmatum*.²⁶ Pharmacological researches show that emodin not only has various pharmacological effects such as antibacterial and fungal infections, anti-inflammatory, antioxidant, anti-allergic, etc, but also can regulate the expression of various cancer-related proteins such as *Akt/mTOR*, *NF-κB*, *HIF1α*, and *STAT3* to achieve the effects of inhibiting cell proliferation and migration, promoting cell apoptosis, and inhibiting multidrug resistance in a variety of malignant tumors.^{23,27,28} In 2013, Zhang et al²⁹ found that the combined use of emodin and gemcitabine significantly reduced the expression of *NF-κB*, *XIAP* and *survivin* in pancreatic cancer cells, thereby making BxPC-3 cells that were originally resistant to gemcitabine have

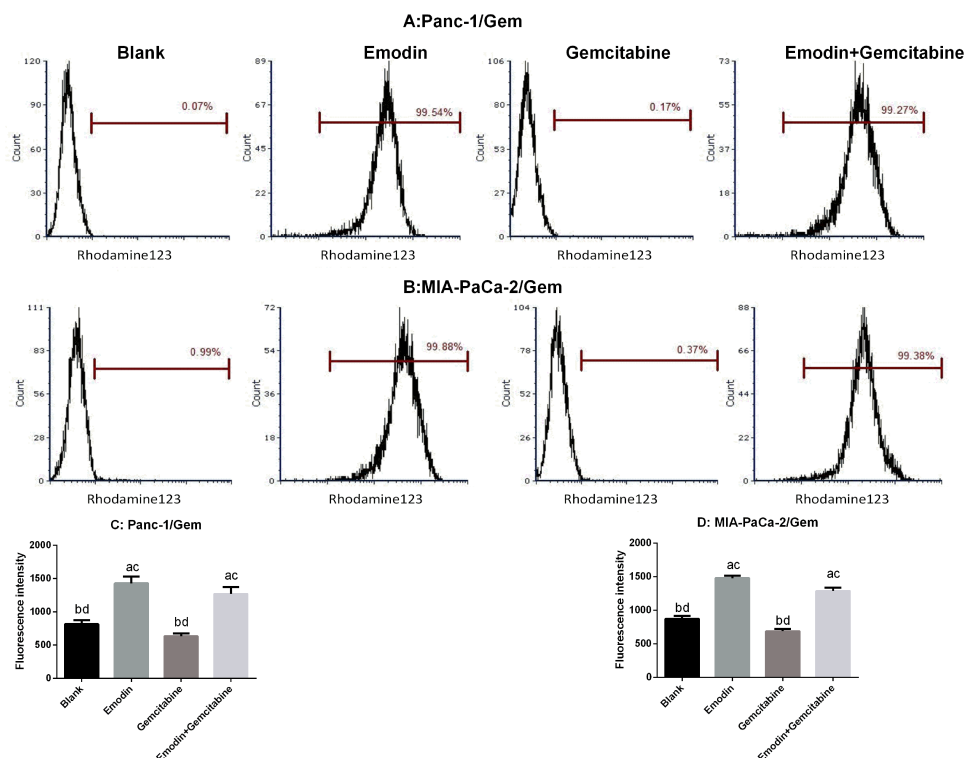

Figure 5 (A and C) Emodin's effect on P-gp function (presented as fluorescence intensity) in Panc-1/Gem cell detected by flow cytometry. **(B and D)** Emodin's effect on P-gp function (presented as fluorescence intensity) in MIA-PaCa-2/Gem cell detected by flow cytometry. ^a $P < 0.05$ compared to the blank group, ^b $P < 0.05$ compared to the emodin group, ^c $P < 0.05$ compared to the gemcitabine group, ^d $P < 0.05$ compared to the emodin+gemcitabine group.

restored sensitivity to gemcitabine.²⁹ Unfortunately, the molecular target of emodin has not been confirmed, which greatly limits the clinical application prospect of emodin as an antitumor drug. In order to determine the target of emodin, we performed computer target prediction experiments on emodin. Through reverse virtual screening of the drugable site database (sc-PDB), which allowed one-to-one docking of emodin with the protein in the data by molecular docking technology, and sorting by docking to select the most potential target. We found that *IKK β* , which is extremely important in the *NF- κ B* signaling pathway, had a higher order. Further structural analysis showed that emodin bound to the allosteric site of the junction of the *IKK β* kinase C-terminal and ubiquitination domain. Based on this finding, we conducted this study, confirming our original hypothesis that emodin down-regulated the expression of *NF- κ B* in drug-resistant cells most likely caused by inhibiting the activity of its upstream kinase *IKK β* .

The *I κ B* kinase (IKK) complex includes the catalytic subunits *IKK α* and *IKK β* and the regulatory subunits *NEMO/IKK γ* . IKK plays an important role in the activation of the *NF- κ B* signaling pathway.³⁰ *IKK β* is the main

catalytic subunit of the IKK complex and is required for inflammatory mediators to activate *NF- κ B*. When exposed to external stimuli such as *TNF- α* , inflammatory factors, ultraviolet light, and lipopolysaccharide, cytokines bind to TNF receptors on the surface of cell membranes, and then TNF receptors multimerize and interact with TRADD in the cytoplasm.³¹ TRADD recruits TRAF and RIP, which passes the signal to IKK. IKK activation phosphorylates Ser32 and Ser36 residues of the α subunit of *I κ B* and Ser19 and Ser23 residues of the β subunit. *I κ B* was then released from the p50/p65/*I κ B* heterotrimer, which was degraded by proteasome after ubiquitination. Furthermore, *NF- κ B* was able to expose its nuclear localization signals (NLS), quickly enter the nucleus from the cytoplasm, and combine with specific sequences on nuclear DNA to initiate or enhance the transcription of related genes and participate in the regulation of inflammation, infection and immune response.³²

I κ B is an inhibitor of *NF- κ B*, including *p100*, *p105*, *I κ B α* , *I κ B β* , *I κ B γ* , *I κ B ϵ* , *Bcl-3*, and *I κ B-R*. Most *I κ B*s contain 3–8 ankyrin repeat motifs at the C-terminus and bind to *NF- κ B* through this motif, covering the nuclear localization sequences (NLS) of the Rel homology domain,

inhibiting NF- κ B activity.³³ The N-terminus of *I κ B* is a signal response region, which contains serine phosphorylation and ubiquitination sites, and plays an important role in the induced degradation of *I κ B*. Normally, NF- κ B p65, p50 in the cytoplasm and inhibitory protein *I κ B* combine to form a trimer complex, and NF- κ B exists in a latent state.^{32,34} In this study, we found that expression of NF- κ B was down-regulated in pancreatic cancer-resistant cell lines under the action of emodin, which is consistent with previous studies. At the same time, we also found that the expression level of IKK β was also significantly down-regulated, which was consistent with the trend of NF- κ B. In contrast, *I κ B- α* expression was up-regulated. These results further confirmed that emodin regulates IKK β to achieve the purpose of regulating NF- κ B, thereby restoring the chemotherapy sensitivity of pancreatic cancer cells. Furthermore, we are still curious to know if emodin can act on cell lines which also have high levels of NF- κ B (such as many other cancer cell lines).

Studies have confirmed that chemotherapy resistance of cancer cells may also be caused by multi-drug resistance gene (*MDR-1*) and its encoded protein P-gp.³⁵ Our previous studies have also confirmed that emodin affected the expression of *MRP* and *P-gp* expression levels. *P-gp*, encoded by *MDR*, is a transmembrane protein and belongs to the ATP-binding cassette transporter protein superfamily.³⁶ It acts as an ATP-dependent drug efflux pump and has been shown to reduce the concentration of intracellular chemotherapeutic agents. *MDR-1/P-gp* plays a very important role in the process of tumor chemotherapy resistance.^{35,37} In this study, rhodamine 123 efflux experiments demonstrated that *P-gp* function was significantly reduced under the action of emodin.

Considering that the relationship between the expression level of apoptosis-related proteins and emodin has been investigated in our previous research, we did not expand the apoptosis part in this study. Our future research will focus on exploring the specific molecular mechanism by which emodin affects the proliferation and apoptosis of pancreatic cancer cells, and try to knock out or overexpress the *IKK β* gene through gene editing technology to observe the effect of this operation on chemotherapy resistance of pancreatic cancer.

In summary, our research confirms that emodin inhibits the expression of *IKK β* , thereby inhibiting the expression and activity of downstream NF- κ B, and inhibits *P-gp* function at the same time, ultimately achieving the purpose of reversing the drug-resistance of pancreatic cancer

cell lines. The combination of gemcitabine and emodin may improve the efficacy of pancreatic cancer patients, reduce the possibility of drug resistance, and further extend the survival of patients with pancreatic cancer.

OncoTargets and Therapy

Publish your work in this journal

OncoTargets and Therapy is an international, peer-reviewed, open access journal focusing on the pathological basis of all cancers, potential targets for therapy and treatment protocols employed to improve the management of cancer patients. The journal also focuses on the impact of management programs and new therapeutic

agents and protocols on patient perspectives such as quality of life, adherence and satisfaction. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
