Objective: Early-onset dementia (EOD) is a relatively uncommon form of dementia that afflicts people before age 65. Only a few studies analyzing the genetics of EOD have been performed in the Chinese Han population. Diagnosing EOD remains a challenge due to the diverse genetic and clinical heterogeneity of these diseases. The aim of this study was to investigate the genetic spectrum and clinical features of Chinese patients with EOD.

Materials and Methods: A total of 49 EOD patients were recruited. Targeted next-generation (NGS) analyses were performed to screen for all of the known genes associated with dementia. Possible pathogenic variants were confirmed by performing Sanger sequencing. The genetic spectrum and clinical features of the EOD patients were analyzed.

Results: Seven previously reported pathogenic variants (p.I213T and p.W165C in *PSEN1*; p.D678N in *APP*; c.1349_1352del in *TBKI*; p.P301L and p.R406W in *MAPT*; p.R110C in *NOTCH3*) and two novel variants of uncertain significance (p.P436L in *PSEN2*; c.239-11G>A in *TARDBP*) were identified.

Conclusion: Our study demonstrated the genetic spectrum and clinical features of EOD patients, and it reveals that genetic testing of known causal genes in EOD patients can help to make a precise diagnosis.

Keywords: Chinese, genetic analysis, early-onset dementia, next-generation sequencing

Introduction

Early-onset dementia (EOD) usually refers to dementia that develops before the patient is 65 years old.¹ It is speculated that genetic factors play a more important role in the pathogenesis of EOD than in late-onset dementia (LOD). EOD is a condition with a high heterogeneity that can be caused by several distinct diseases with different etiology and pathophysiology, including Alzheimer's disease (AD), frontotemporal dementia (FTD), dementia with Lewy bodies (DLB), and other neurodegenerative brain disorders.²⁻⁵

AD is the most common type of dementia. Hallmarks of AD include the extracellular deposition of amyloid beta (A β) peptides and the formation of intra-neuronal neurofibrillary tangles (NFTs), which leads to irreversible neuron loss and loss of memory.⁶ The pathogenesis of AD remains unclear, and both genetic and environmental factors contribute to its risk.⁷ Approximately 95% of AD patients are sporadic while the remaining are familial AD patients (FAD). Pathogenic variants in amyloid precursor protein (*APP*), presenilin 1 (*PSEN1*) and presenilin 2 (*PSEN2*) have been previously identified as causes of FAD.⁸ Several studies have been

Correspondence: Zhi-Ying Wu;
Qing-Qing Tao
Email zhiyingwu@zju.edu.cn;
qingqingtao@zju.edu.cn

performed to determine how pathogenic variants in these three genes contribute to AD, thus providing insight into the pathogenesis of AD.⁹

FTD is another type of dementia that has neuropathological and clinical crossover with AD. FTD primarily affects the frontal and temporal lobes of the brain, and it is generally associated with dysfunction of the personality, behavior and language use.¹⁰ DLB is also a common cause of dementia. The characteristic clinical symptoms of DLB include fluctuating cognition, recurrent visual hallucinations, and Parkinsonism.¹¹ Other neurologic diseases, such as amyotrophic lateral sclerosis (ALS), Parkinson's disease (PD), and prion diseases, can also present with EOD. With an increasingly aged population, more attention has been given to dementia.¹² However, diagnosing EOD remains a challenge due to the diverse genetics and clinical heterogeneity of these diseases.

Next-generation sequencing (NGS) has been used to examine EOD patients with an unknown diagnosis.^{13–15} However, genetic studies on EOD have been rarely performed in the Chinese population.¹⁶ In this study, NGS of 70 genes associated with dementia was performed for 49 Chinese patients with EOD, and we identified 2 novel variants of uncertain significance (VUS) and 7 previously reported pathogenic variants.

Materials and Methods

Subjects

All of the patients in our study were recruited from the Department of Neurology, second affiliated Hospital of the Zhejiang university school of medicine from May 2015 to July 2019. A total of 49 EOD patients satisfied the following inclusion criteria for our study: 1) had early disease onset (<65 years old) and 2) had a phenotype of dementia. The exclusion criteria for our study: 1) had a disease or impairment of the central nervous system, including active or past subdural hematoma, active or past subarachnoid hemorrhage, and primary or metastatic brain cancer; or 2) had other systemic diseases that may result in cognitive impairment, including neurosyphilis, addiction to alcohol, drug use, vitamin deficiency and thyroid dysfunction. Subjects who had non-neurological diseases that may result in cognitive impairment were also excluded. Clinical evaluations and neurological examinations were performed by two senior neurologists. The criterion for a probable AD diagnosis was set according to the National Institute on Aging-Alzheimer's Association (NIAAA).¹⁷

The criterion for a probable FTD and DLB diagnosis was set according to previous studies.^{18,19} This study was approved by the Ethics Committee of Second Affiliated Hospital, Zhejiang University School of Medicine. Written informed consent for participation in this study and publication of their clinical details was obtained from all of the participants or their legally authorized caregivers.

Targeted Next-Generation (NGS) Panel Analysis Screening

Blood samples were collected from all patients. Genomic DNA was extracted from the peripheral blood using a Blood Genomic DNA Extraction Kit (Qiagen, Hilden, Germany) according to standard procedures. A customized multigene panel that contained genes associated with dementia was designed (Table S1). NGS panel screening was performed using the Illumina HiSeq2000 platform (XY Biotechnology Co Ltd, Hangzhou, China). Publicly available databases including the Single Nucleotide Polymorphism Database (dbSNP) (<https://www.ncbi.nlm.nih.gov/snp/>), the 1000 Genomes Project (<https://www.ncbi.nlm.nih.gov/variation/tools/1000genomes/>), and the gnomAD browser (<https://gnomad.broadinstitute.org/>) were used to extract information about the detected variants. Three software programs, SIFT, PolyPhen2 and Mutation Taster, were used to predict the possible protein functional changes.

Sanger Sequencing and APOE Genotyping

Possible pathogenic variants were confirmed by performing Sanger sequencing with an ABI 3500XL DX Genetic Analyzer (Applied Biosystems, Foster City, CA, USA) following the procedure described in our previous study.²⁰ A co-segregation analysis was performed for all available familial members. The *APOE* genotypes were determined by multiplex amplification refractory mutation system PCR according as previously described.²⁰

Results

Demographic Data of the EOD Patients

A total of 49 unrelated EOD patients were included in our study. The mean age at onset (AAO) of the EOD patients was 52.9 ± 7.8 years. Of these patients, 42.9% were male and 57.1% had a positive family history (at least 2 family members in the last three generations were affected by dementia). The mean AAO of the probands with familial

dementia was 52.8 ± 8.8 years. A total of 30.6% carried one APOE ϵ 4 allele, and 18.4% carried two APOE ϵ 4 alleles. The personal and medical histories of all 49 EOD patients are summarized in Table 1.

Identification of Variants

Targeted NGS was performed in this study. Coverage of the fraction of target bases indicated that 99.47% of the target bases had $>30\times$ coverage and that 98.83% of target bases had $>50\times$ coverage. The mean coverage of target bases ranged from 597.39 to 1313.36. After filtering, 9 variants in 7 known genes associated with EOD were identified in 9 index patients. Two variants (p.P436L in *PSEN2*; c.239-11G>A in *TARDBP*) were novel and 7 variants (p.I213T and p.W165C in *PSEN1*; p.D678N in *APP*; c.1349_1352del in *TBKI*; p.P301L and p.R406W in *MAPT*; p.R110C in *NOTCH3*) were previously reported.^{19–22} The presence of these variants was confirmed by Sanger sequencing and subsequent segregation analysis. Neither the 2 novel variants were detected in 500 healthy Chinese subjects. According to the American College of Medical Genetics and Genomics (ACMG) standards,²¹ the 2 novel variants were classified as VUS variants. Of 49 EOD patients, 7 (14.28%) were found to carry disease-causing mutations and two were found to carry uncertain significance variants (Table 2).

Clinical Features of Patients Carrying *PSEN1*, *APP* and *PSEN2* Variants

Two previously reported pathogenic variants in *PSEN1* were identified in the two probands from Family 1 and Family 2. Case 1 (II-6 in Family 1) (Figure 1A), carrying the pathogenic variant p.I213T (c.638T>C) (Figure 1C) in *PSEN1*, is a 46-year-old woman who showed progressive memory impairment that began six years ago. At that time, she struggled to remember the way home and often forgot the location of frequently used items. As her cognitive abnormality progressed, she became irritable. She could not finish the mini-mental state examination (MMSE), Montreal cognitive assessment (MoCA) or CDR due to un-cooperativity. Her mother (Family 1, I-2) and elder brother (Family 1, II-1 and II-3) had similar clinical presentations. However, none of them was available for genetic evaluation. A pathogenic variant p.W165C (c.495G>T) in *PSEN1* was identified in case2 (II-4 in Family 2) (Figure 1B and D). Case 2 is a 53-year-old woman who developed progressive memory impairment

that began five years ago. The symptoms of memory decline became worse over the last few years. Over the past year, she started to exhibit emotional instability and gradually developed poor language expression, slow movement and poor execution. Her MMSE score was 6/30, and her MoCA was difficult to obtain due to a lack of cooperativity. Brain MRI analysis revealed global brain atrophy without vascular lesions. Similar clinical characteristics were reported for her father who died at 55 years old (Family 2, I-2).

The pathogenic variant p.D678N (c.2032G>A) in *APP* was identified in a 51-year-old woman (Family 3, II-2, case 3) (Figure 1E and G). Her initial symptom was a progressive decline of memory deficits that began at age 42 years. She sought care at a local hospital, was diagnosed with AD, and began treatment with donepezil. Over the next 9 years, her symptoms progressively worsened. She started to exhibit emotional instability and was reluctant to take part in social activities. Now, she has lost the ability to take care of herself in daily life. She could not cooperate to complete the MMSE or the MoCA. MRI revealed an abnormally high signal from the white matter in T2-weighted images as well as global brain atrophy. The patient's mother (Family 3, I-2) had similar clinical presentations at 62 years old and died one year later.

A novel VUS variant p.P436L (c.1307C>T) in *PSEN2* was identified in a 56-year-old man (Family 4, III-3, case 4) (Figure 1F and H) who presented with short-term memory impairment, a decline of visual construction abilities, deficits in calculation abilities, and mild personality changes at the age of 52 years. His MMSE and MoCA scores were 14/30 and 10/30, respectively. Brain MRI indicated atrophy of the bilateral temporal lobe and hippocampus. Similar clinical characteristics were reported for his mother (Family 4, II-2), mother's brother (Family 4, II-3) and mother's sister (Family 4, II-5), as well as his own elder brother (Family 4, III-1) and three sisters (Family 4, III-6, 8, and 10). This variant was absent in the 500 healthy Chinese subjects that were tested. His family members, however, refused genetic evaluation. This variant is classified as VUS according to the ACMG standards.

Clinical Features of Patients Carrying *TBKI*, *MAPT* and *TARDBP* Variants

Case 5 (II-6 in Family 5) (Figure 2A) was a 51-year-old man who was referred to our hospital following a three-year

history of progressive memory impairment, language deficits, slowness in reaction time and changes in personality. He had a family history of dementia, as both his mother and brother had similar clinical characteristics. A pathogenic variant p.I450Kfs (c.1349_1352del) in *TBKI* was identified by NGS analysis and confirmed with Sanger sequencing (Figure 2B). During his last physical examination, the patient showed less cooperation, and amnesic aphasia. There was no muscle atrophy; muscle strength, muscle tone and deep tendon reflexes were normal. Cerebral MRI showed bilateral atrophy of the frontal lobe, temporal lobes and hippocampus, and no obvious Aβ deposition was found by [11C]-PIB PET imaging (Figure 2C and D).

Both Case 6 (II-13 in Family 6) (Figure 2E) and case 7 (II-6 in Family 7) (Figure 2G) carried a pathogenic variant in *MAPT*. Case 6, carrying a pathogenic variant p.R406W (c.1216C>T) (Figure 2F), was a 63-year-old woman who came to our Neurology clinic with a complaint of mild memory impairment over the past four years. Her MMSE and MoCA scores were 23/30 and 14/30, respectively. Similar clinical characteristics were reported for her mother (Family 6, I-2) and three sisters (Family 6, II-3, II-5, and II-9). Case 7, carrying a pathogenic variant p.P301L (c.902C>T) (Figure 2H), was a 49-year-old woman who presented with memory impairment as well as a decline of language and calculation abilities at the age of 46. One year later, slowness in reaction times and changes in personality were observed by her husband. During her last physical examination, which was three years after the disease onset, the patient showed less cooperation, hyperactivity, and emotional instability. The patient could not cooperate to finish the Frontal Behavioral Inventory, MMSE or MoCA. Cerebral MRI showed bilateral atrophy of the hippocampus. Her brother and nephew had a similar clinical presentation.

A novel VUS variant c.239-11G>A in *TARDBP* was identified in a 60-year-old woman (Family 8, III-3, case 8) (Figure 2I and J) who presented with memory impairment. Her symptoms gradually got worse, and one year after disease onset, she could not remember the way home or how to prepare food. She also presented with a decline in calculation and language abilities as well as changes in personality. Her MMSE score was 3/30 and her MoCA score was 0. Brain MRI showed bilateral atrophy of the hippocampus. She has a positive family history as her mother and brother both have similar symptoms. However, her family members were unavailable for

Figure 2 Pedigree charts and variants identified in Family 5-9. (A, E, G, I, K) Pedigree charts of Family 5-9; (C) Cerebral MRI of case 5; (D) [^{11}C]-PIB PET imaging of case 5; (B, F, H, J, L) Sequencing chromatograms of the variants in *TBK1* (p.I450Kfs), variants in *MAPT* (p.R406W and p.P301L), variants in *TARDBP* (c.239-11G>A) and variants in *NOTCH3* (p.R110C).

genetic evaluation. This variant is classified as VUS according to the ACMG standards.

In addition, a variant p.R110C (c.328C>T) in *NOTCH3* was identified in a 29-year-old man (Family 9, II-3, case 9) (Figure 2K and L) who presented with mild memory impairment. His MoCA score was 21. Brain MRI showed bilateral frontoparietal lobe and paraventricular white matter lesions. His mother (Family 9, I-2) had experienced 20 year history of memory decline starting when she was 36 years old. She had a cerebral infarction in her 40s. This variant in *NOTCH3* was reported previously to be pathogenic; therefore, this patient was diagnosed with cerebral

autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL).

Discussion

EOD is a condition caused by several diseases with extensive genetic and clinical heterogeneity. Making a specific diagnosis of EOD remains a challenge. Many of EOD patients do not have a precise clinical diagnosis. The genetic analysis of patients with EOD has been investigated extensively in the Caucasian and Korean populations but rarely in the Chinese population. In the present study, we performed NGS and Sanger sequencing to identify the genetic etiology

of 49 EOD patients. Two novel VUS variants (p.P436L in *PSEN2*; c.239-11G>A in *TARDBP*) and 7 previously reported pathogenic variants (p.I213T and p.W165C in *PSEN1*; p.D678N in *APP*; c.1349_1352del in *TBK1*; p.P301L and p.R406W in *MAPT*; p.R110C in *NOTCH3*) were identified in 9 EOD patients.

In our study, of the 49 indexed EOD patients, 14.28% carried pathogenic variants. In a recent study of 221 Belgian patients with EOD, 2.84% of the patients had a pathogenic variant in *APP*, *MAPT*, *SOD1*, *TBK1*, and *C9orf72*.¹⁴ A previous study performed genetic analysis of a cohort of Koreans with early-onset AD (EOAD) by NGS; pathogenic variants were identified in 6% of the 67 EOAD patients.²² Similarly, in another study that included 60 APOE ε4 non-carrying Korean patients with EOAD, 8.3% of the patients were found to carry likely pathogenic variants.²³ Additionally, pathogenic variants have been identified in 5% of early-onset AD and FTD patients from Korea.¹³ Compared with these studies, the frequency of pathogenic variants (14.28%) was higher in our study. One of the explanations for this discrepancy is that the proportion of patients with a positive family history was relatively high (54%) in our study. In a recent study, *PSEN1*, *PSEN2*, and *APP* mutations were identified in a Chinese cohort that contained 1330 patients with AD or MCI in 404 pedigrees; 16.83% of these patients carried *PSEN1*, *PSEN2*, or *APP* mutations, comparable with the rate in the present study.²⁴

Among all of the identified patients, three patients each had AD and FTD. AD and FTD are two common neurodegenerative diseases. There is a neuropathological and clinical crossover between these two diseases. For example, similar clinical presentations such as a decline in memory, personality changes, and phosphorylated tau protein deposition can be observed in both diseases. In this study, case 3, who carried a pathogenic variant in *APP*, exhibited personality changes and short-term memory impairment, whereas case 6, who carried a pathogenic variant in *MAPT*, demonstrated only mild memory impairment four years after disease onset. Similarly, a recent study has reported FTD patients with typical AD clinical presentations.²⁵ It is difficult to discriminate between these two diseases if patients have an atypical clinical presentation. Thus, it is worthwhile to perform NGS in EOD patients, especially those with a positive family history, to help formulate a genetics-based diagnosis.

TBK1 is a causative gene of FTD-ALS that has been recently identified.^{26,27} Its encode protein, tumor necrosis factor receptor associated factor NF-κB activator-binding

kinase 1 (*TBK1*), is a serine/threonine protein kinase that participates in multiple cellular pathways including neuroinflammation²⁸ and selective autophagy degradation.²⁹ A pathogenic variant in *TBK1* p.I450Kfs (c.1349_1352del) was identified in case 5. This variant has been previously reported in patients with ALS.²⁶ Very few studies have linked *TBK1* with FTD in Chinese populations.^{25,30} To the best of our knowledge, this is the first study to link this variant with FTD in the Chinese population.

The majority of EOD cases in our study remain genetically unexplained, indicating additional causal and risk genes need to be identified. In this NGS study, 2 novel uncertain significance variants in the *PSEN2* and *TARDBP* genes were identified. The role of these 2 variants needs to be determined in the future.

Conclusion

In conclusion, 7 previously reported pathogenic variants and 2 novel VUS variants were identified in the present study. All of the identified patients had early onset and a positive family history of dementia. Our study expanded the genetic spectrum of EOD and reveals that NGS is a great help in the definite diagnosis of EOD patients.

Clinical Interventions in Aging

Publish your work in this journal

Clinical Interventions in Aging is an international, peer-reviewed journal focusing on evidence-based reports on the value or lack thereof of treatments intended to prevent or delay the onset of maladaptive correlates of aging in human beings. This journal is indexed on PubMed Central, MedLine, CAS, Scopus and the Elsevier

Bibliographic databases. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
