Purpose: The comprehensive and free Healthy Kids Initiative (HKI) was developed with key features including social support, family support, and cognitive behavior education in order to promote program completion and improve health outcomes among youth. The first objective was to determine program completion rates and independent risk indicators for non-completion. The second objective was to determine the 12-week impact of the Healthy Kids Initiative on aerobic fitness, depressed mood and health-related quality of life.

Patients and Methods: Obese youth (ages 10–17) were referred to a community-based, multidisciplinary, free program by their doctor or pediatrician. Each participant was requested to attend the program with a “buddy” and complete three social support contracts with family and friends to support their behavioral modifications. The program duration was 12 weeks with physical activity, dietary, and cognitive behavior education sessions. Those who completed the program, and those who did not, were compared across socioeconomic variables, age, gender, depressed mood and aerobic fitness.

Results: Across five cohorts, 1789 of 1995 youth completed the program (89.7% completion rate). Five referred youth never started. Independent risk indicators associated with non-completion included older age (OR 3.07, 95% CI 2.26–4.17; $p < 0.001$), mother with a non-professional occupation (OR 1.84, 95% CI 1.22–2.78; $p = 0.004$), and living in a low-income neighborhood (OR 9.37, 95% CI 5.61–15.65; $p < 0.001$). There were significant improvements from baseline for aerobic fitness (mCAFT score 35.84 to 55.72 $\text{mL} \times \text{kg}^{-1} \times \text{min}^{-1}$; $p < 0.001$), depressed mood (mean CES-D 12 score 21.47 to 17.40; $p < 0.001$), and health-related quality of life (mean SF-12 score 23.4 to 33.8; $p < 0.001$).

Conclusion: The HKI program had high completion rates and early success in improving outcomes. Knowing the independent risk indicators for non-completion will allow for program revision to help at-risk participants complete the program.

Keywords: adolescent, community-based, obese, aerobic fitness, adherence, physical activity

Introduction

There is little doubt that being overweight or obese in youth is a significant public health concern. According to an analysis of objective measures of body mass index (BMI) as well as self-reported data of height and weight among Canadian youth, 23.3% of children were overweight or obese in 1978/79, and the prevalence increased to 31.4% by 2012/13.¹ Obesity prevalence climbed from 12.3% in 2004 to 16.6% in 2012/13 among youth 12–17 years.¹ This trend has been the target of various public health and research initiatives to increase physical activity and promote healthier diets.²

The implications for obesity in youth are serious. A 2015 study by the American Heart Association found early signs of cardiovascular disease in obese children when compared to non-obese children.³ Further, the life expectancy of adults across

high-income countries has recently declined, with obesity cited as one contributing cause for the reduction.⁴ The psychological implications are also important, with obesity in youth as a risk factor for depression and anxiety. One study found a 43% increased risk of depression and anxiety among obese female youth and a 33% increased risk among obese male youth.⁵

Numerous programs to reduce weight in obese or overweight adolescents have been developed in the past 20 years, with varying degrees of success in reducing weight,^{6–9} improving body composition,⁹ and even improving mental health and quality of life.^{7,8} However, many of these programs have had moderate to high rates of attrition. For example, one study found attrition rates ranging from 27% at 12-weeks to 73% at 9–12 months.¹⁰ Without paying due attention to adherence and drop-out, well-designed interventions are limited in their effectiveness.

Enough research exists on improving physical activity in youth for a group of researchers to have developed ten practical lessons for generating success in programs designed to increase physical activity rates in overweight and obese children and adolescents.¹¹ These supports include parent social support, applying a multidisciplinary approach, invoking a sense of fun, including variety, promoting a welcoming setting, and accounting for the individual physical and psychosocial characteristics of the participants.¹¹

The Healthy Kids Initiative (HKI) is a comprehensive behavior modification program aimed at obese youth to improve health, mental health and well-being. It was built with extensive community consultation and fulfills the social support needs of youth participants at no cost.¹¹ These measures were designed to enhance the quality of the program, while also encouraging completion on the part of the individual.

Study Objectives

The first objective was to determine program completion rates and independent risk indicators associated with program non-completion. The second objective was to determine the 12-week impact of the Healthy Kids Initiative (HKI) on aerobic fitness, depressed mood, and health-related quality of life. Weight loss was not an objective of the program in order to keep a positive focus on health and behaviors and to not discourage adherence.

Materials and Methods

Intervention

The Healthy Kids Initiative (HKI) offered a 12-week program to 2000 obese youth between the ages of 10 and 17 to achieve measurable changes in health, mental health and behavioral outcomes through increased physical activity, healthy eating, cognitive behavior education, and social support. The prospective, longitudinal cohort was offered in the cities of Moose Jaw, Regina, and Saskatoon, in the province of Saskatchewan, Canada, through the local not for profit YMCA fitness facilities.

The development of the 12-week HKI program benefited from community consultation with over 200 family physicians, pediatricians, cardiologists, internists, mayors, police chiefs, school board officials and teachers being consulted prior to intervention. Youth participants were referred by their own family physician or paediatrician.

Participants

Children and youth aged 10–17, who were obese as determined by their body mass index (score over 30), and deemed safe to participate in the intervention by their referring family doctor or pediatrician, were invited to participate. The only inclusion criteria was that the program must be safe for the participant to attend.

Procedures

Youth participated in daily physical activity five times per week supervised by a kinesiologist (who also monitored activity type and duration), group dietary education provided by a registered dietician once per week, group cognitive behaviour education provided by a social worker or psychologist once per week, along with social support from the health provider team. Each participant was asked to attend all sessions with a “buddy” for social support and each participant was asked to sign three social support contracts with family members or friends to encourage program completion. For example, if a youth was unsure as to who was providing transportation for the program, a family member or friend was asked to sign a transportation agreement prior to program initiation. Electronic swipe cards to enter the fitness facilities were used to capture program attendance of each participant.

Additional support was also provided through The Daily Difference smartphone app, which could be used at any time to help participants with goal setting, self-address

mental health concerns, practice cognitive behavior skills, and also chat directly with health-care providers.

All youth signed an informed consent form prior to participating with a parent or guardian as a witness. The project was approved annually on ethical grounds by the Saskatchewan Health Authority (REB-18-63). This study was conducted in accordance with the Declaration of Helsinki.

Measures

The primary outcome of the study was to determine completion rates, and independent risk indicators associated with non completion. The secondary outcomes of the HKI were not weight loss, but instead focused on health outcome changes in aerobic fitness, depressed mood and health-related quality of life.

Self-esteem was measured with four questions taken from the Self-Description Questionnaire III, and asked participants to give an answer of false; mostly false; sometimes true, sometimes false; mostly true; or true to each of the four statements: 1) In general, I like the way I am, 2) Overall, I have a lot to be proud of, 3) A lot of things about me are good, and 4) I like the way I look.¹² These items were used in multiple iterations of the National Longitudinal Survey of Children and Youth by Statistics Canada.¹³

Health-related quality of life (HRQL) was measured using the shortened version of the Short-Form 36 Health Survey (SF-36).¹⁴ The SF-12 is a brief, psychometrically sound measure of quality of life. Scores measure two dimensions: physical and mental health. The SF-12 has comparable validity and reliability as its predecessor,¹⁵ which has been considered the generic measure of choice in obesity research by the United States Task Force on Developing Obesity Outcomes and Learning Standards (TOOLS).¹⁶

Depressed mood was measured using the 12-item Centre of Epidemiological Studies Depression scale (12-item CES-D). The scale asks individuals to rate the frequency at which they have felt certain things in the past two weeks. The 12-item CES-D was used in the National Longitudinal Study of Children and Youth, and at the time established three categories of depressive symptoms among adolescents. Scores of 0–11 indicated minimal depressed mood; scores of 12–20 indicated somewhat elevated depressed mood and a score of 21–36 indicated very elevated depressed mood.¹⁷

Aerobic Fitness was determined using the modified Canadian Aerobic Fitness Test (CAFT), which has been deemed as an acceptable measure of aerobic fitness with youth aged 10–15 years, having previously tested as comparable to the run/walk test.¹⁸ The modified CAFT protocol includes three minutes of stepping up and down a standardized staircase. Depending on heart rate at each three-minute interval, there are up to a maximum three stages (nine minutes of stepping maximal), with each stage increasing in pace. Participant heart rates are measured after each stage for 10 seconds, and results are presented as an indicator of maximum oxygen consumption adjusted for body weight ($\text{mL} \times \text{kg}^{-1} \times \text{min}^{-1}$).¹⁸ For males aged 8 to 14 years, the Canadian general population median is $57 \text{ mL} \times (\text{kg} \times \text{min}^{-1})$. For males 15 to 19 years, the median is 53. For females 8 to 14 years, the median is 50, and for females 15 to 19, the median is 43.¹⁹

Dietary questions were taken from the National Longitudinal Survey of Children and Youth developed by Statistics Canada.¹³

Socioeconomic status was determined by parental education level, occupation, and neighborhood income (as determined by Statistics Canada census data by using postal code).²⁰

All participants were screened at baseline and at the completion of the program (12 weeks).

Analysis

Using SPSS (v. 27) mean scores of each measure were calculated and compared using paired sample t-tests (significance tested at $p < 0.05$). Categorical variables were compared via cross-tabulations to determine any significant associations between completers and non-completers and among those whose depressed mood improved after the program and those who remained depressed. Significant differences were determined using Chi-square test ($p < 0.05$). For logistic regression analysis to determine independent risk indicators of program completion, the unadjusted effect of each covariate was determined and then entered one step at a time based on changes in the $-2 \log$ likelihood and the Wald test.²¹ The final results are presented as adjusted odds ratios with 95% confidence intervals (CIs).

As part of a funding agreement with the Public Health Agency of Canada, an External Evaluation Specialist, and an External Evaluator, were hired. As such, a research manager and the Director of the Canadian Hub for Applied and Social Research (CHASR) at the University of Saskatchewan were

contracted. This unit is governed by a management committee that includes a Chair, the Vice President Research of the University and the Dean or Executive Director from all 19 colleges on campus. At the end of each cohort, the Director of the CHASR was asked to sign a form to independently validate the accuracy of the data.

Results

Two thousand youths were referred to the program from January 1, 2019, to June 30, 2020, across the three sites. Five of the referrals never began the program. Among those who participated in the program, 1789 out of 1995 completed the 12 weeks (adherence rate of 89.7%). The mean age was 14.5 years with a high proportion being 14 or older (72.3%). Slightly over half (52.4%) were female. The majority of participants' fathers (86.6%) and mothers (75.5%) were college or university educated. Almost all parents were employed, with 72.2% of fathers and 68.4% of mothers employed in non-professional positions, and 17.3% of fathers and 23.2% of mothers working in professional positions. Those who were unemployed were students (10.5% of fathers and 8.4% of mothers). Finally, 86.6% of participants resided in middle-income neighborhoods, with others being from high income (11.3%) and low income (2.1%) neighborhoods. The percentage of Saskatchewan youth living in low-income neighborhoods, according to the 2016 Census, was 17.8% and, as such, low-income youth were underrepresented in the sample of program participants.²⁰ The demographic distribution of participants is presented in Table 1.

Completion

Program completion was defined as being an active participant up to follow-up testing as 12 weeks. Those who completed the program (n=1789) were compared to those who did not (n=206) across demographic variables, baseline depressed mood, and baseline modified CAFT scores. Prior to adjustment, age, gender, mother's education level, father's and mother's occupational status, and neighborhood income were all significantly associated with not completing the program (Table 2). Higher scores on the 12-item CES-D were also associated with non-completion, as well as lower baseline modified CAFT scores ($p<0.001$ for both).

After binary logistic regression, three covariates were independently associated with program completion. Older age (odds ratio 3.07, 2.25–4.17 CI; $p<0.001$), non-professional maternal occupation (odds ratio 1.84, 1.22–2.78 CI; $p=0.004$) and being from a low-income neighborhood all had a negative association with program completion (odds ratio 9.37, 5–61–

Table 1 Demographics of Healthy Kids Initiative Participants, Groups 1–5 (n = 1789 Out of 1995)

Demographic Variables	n (%)
Age (mean): 14.5

Neighborhood income (as determined by census data, postal code)	
High income	203 (11.3%)
Middle income	1549 (86.6%)
Low income	37 (2.1%)

15.65 CI, $p<0.001$; Table 3). Among those who completed the program, youth participants attended an average of 49 out of 60 supervised exercise sessions, 11 out of 12 dietary education sessions and 9 out of 12 cognitive behavior education sessions.

Aerobic Fitness

Participating in the exercise sessions of the program increased moderate to vigorous physical activity significantly. At baseline, the average amount of moderate physical activity that participants were reporting was 9.45 minutes per week, and 8.13 minutes of vigorous physical activity per week. After 12 weeks, the mean for moderate physical activity increased to 178.91 minutes per week. Vigorous physical activity increased to 226.13 minutes per week. Differences were statistically significant ($p<0.001$). With the increased physical activity, participants also

Table 2 Demographics, Depressed Mood (12 Item CES-D) Score, and Aerobic Fitness (mCAFT) of Those Who Completed the Program at Baseline (n=1789) Compared to Those Who Did Not Complete the Program (n=206)

Variable	Completed Program n=1789	Did Not Complete n=206	p-value
Age (mean)	14.5 years	13.3 years	<0.001
13 and younger	581 (32.5%)	120 (58.3%)	
14 and older	1208 (67.5%)	86 (41.7%)

Professional	310 (17.3%)	22 (10.7%)	
Non-professional	1479 (82.7%)	184 (89.3%)	
Mother occupation			0.005
Professional	415 (23.2%)	30 (14.6%)	
Non-professional	1374 (76.8%)	184 (85.4%)	
Neighborhood income (as determined by census data, postal code)			<0.001
High/middle income	1752 (97.9%)	171 (83.0%)	
Low income	37 (2.1%)	35 (17.0%)	
12 item CES-D Mean (SD)	1.47 (5.36)	21.38 (4.14)	<0.001
No depressed mood	345 (19.3%)	21 (10.2%)	
Depressed mood	1444 (80.7%)	184 (89.3%)	
Missing	0	1 (0.5%)	
Modified CAFT Mean (SD)	35.84 mL*kg ⁻¹ *min ⁻¹ (4.80)	29.86 mL*kg ⁻¹ *min ⁻¹ (6.54)	<0.001

experienced an increase in aerobic fitness. Mean modified CAFT scores at baseline were 35.84 mL×kg⁻¹×min⁻¹ (SD=4.80) and after 12 weeks, the mean score was 55.72 mL×kg⁻¹×min⁻¹ (SD=7.49). Again, this difference was statistically significant (p<0.001). In all, 76.5% of participants increased their CAFT from below the national average for their gender and age group to meet or exceed the national average after 12 weeks.

Health-Related Quality of Life (HRQL)

HRQL increased significantly from baseline to 12 weeks (Table 4). Mean scores across all dimensions increased by 44.4% (p<0.001) with dimensional increases from 23.1% (Role Physical) to 58.1% (Physical Functioning); with all improvements being statistically significant (p<0.001). Reports of very good to excellent general health increased from 5.6% to 57.4% after 12

weeks, while poor health decreased from 19.6% of participants to almost none of the participants (0.2%). Any interference of normal work or activities in the past four weeks decreased from 94.4% of the participants at baseline to 69.5%, and that proportion was split over “a little bit” and “moderately” only.

Self-Esteem

Responses for each self-esteem variable were assigned a value (0 = False; 1 = Mostly False; 2 = Sometimes true, sometimes false; 3 = Mostly True; and 4 = True). Each statement is worded positively, and higher scores are indicative of a higher sense of self-esteem. Mean scores on each of the four items were compared at baseline and after 12 weeks. Scores on all items improved, and the difference was statistically significant across participants (Table 5).

Table 3 Independent Covariates Associated with Non-Completion of the HKI at 12 Weeks. Reference Categories: Age = 13 and Younger; Maternal Occupation = Professional; Neighborhood = High/Medium Income

Variable	Adjusted Odds Ratio*	95% CI	p-value
Age Older age	3.07 (2.90)	2.26-4.17	<0.001
Mother occupation Non-professional/other	1.84 (1.77)	1.22-2.78	0.004
Neighborhood Income Low Income	9.37 (23.34)	5.61-15.65	<0.001

Note: *The unadjusted odds ratios for age, mother occupation and neighborhood income appear in brackets beside the adjusted odds ratios.

Abbreviations: HKI, Healthy Kids Initiative; SF-12, Short-form 12; CES-D, Center for Epidemiological Studies Depression; mCAFT, modified Canadian Aerobic Fitness Test.

Table 4 Health-Related Quality of Life (SF-12) at Baseline Compared to 12-Week HKI Program Completion

Health-Related Quality of Life (SF-12)	Baseline Mean (SD)	12-Week Mean (SD)	Absolute Change	% Change	p-value
Overall	23.4 (2.41)	33.8 (2.95)	+10.4	44.4%	<0.001
Physical functioning	3.1 (0.68)	4.9 (0.91)	+1.8	58.1%	<0.001
Role Physical	2.6 (0.67)	3.2 (0.85)	+0.6	23.1%	<0.001
Role Emotional	2.3 (0.65)	3.2 (0.75)	+0.9	39.1%	<0.001
Mental Health	5.5 (1.06)	7.2 (1.30)	+1.7	30.9%	<0.001

Depressed Mood

Depressed mood mean scores decreased overall from baseline to follow-up (21.47 decreased to 17.4 over 12 weeks; $p < 0.001$). At the start of the program, only 1.6% of participants had no indication of depressed mood, at the end of the program, the percentage increased to 7.2%. What is

more, is that the percentage of participants with very elevated depressed mood decreased from 60.4% to 23.6%. The percentage of participants whose mood improved at least 10% from baseline to follow-up was 65.2%. Increases of 25% or more were observed among 26.6% of participants (Table 6).

Table 5 Self-Esteem Scores and Distribution at Baseline Compared to 12-Week HKI Program Completion

Self-Esteem Variable	Baseline n (%)	12-Week n (%)	p-value
In general, I like the way I am [Mean (SD)]	1.65 (0.64)	2.66 (0.72)	<0.001
False, mostly false	679 (37.4%)	108 (6.0%)	
Sometimes true, sometimes false	1036 (57.9%)	544 (30.4%)

True, mostly true	173 (9.7%)	673 (37.6%)	
I like the way I look [Mean (SD)]	0.45 (0.66)	2.49 (0.71)	<0.001
False, mostly false	1639 (91.6%)	6 (0.3%)	
Sometimes true, sometimes false	146 (8.2%)	933 (52.2%)	
True, mostly true	4 (0.2%)	850 (47.6%)	

Discussion

The Healthy Kids Initiative is a multidisciplinary, community-based behavioral modification program for overweight and obese adolescents. The program has had promising short-term results in improving health-related quality of life, self-esteem, depressed mood, and aerobic fitness. However, these results are only evident if participants can successfully complete the program. The completion rate of HKI is nearly 90%, which is higher than other multi-disciplinary weight loss or behavior modification interventions targeted at youth.¹⁰ For example, other multidisciplinary programs that include physical activity and dietary intervention have had completion rates ranging from 53% at six months,²² 58% at 20 weeks,²³ and 73% at 12 weeks.²⁴

Other studies of adolescent-focused weight loss or behavior modification interventions have found a number of predictors of adherence. For example, a systematic review of barriers and facilitators to community-based behavior modification programs for overweight/obese adolescents found that a family-centered approach to weight loss, supportive program staff, practical sessions (rather than solely educational sessions), social support, a behavioral modification focused approach, and parental concern were important variables.²⁵

Another systematic review reviewed ten studies of weight-loss interventions for adolescents and found a number of variables associated with dropout, including (but not limited to) higher baseline BMI, obesity-related medical conditions, depressive symptoms, behavioral problems, and not having Medicaid insurance.¹⁰

In our study, factors that increased the risk of program non-completion included living in a low-income neighborhood. Living in a low-income neighborhood is a lower socioeconomic status indicator as well as having a mother with a non-professional (possibly lower-paying occupation, with less flexibility). Lower socioeconomic status has been repeatedly demonstrated as a risk indicator for poorer health outcomes in youth (including in obesity).²⁶

Its effect here on program completion could be through multiple pathways, such as struggling to access reliable transportation. Limited transportation has been associated with non-completion in other weight reduction programs targeting obese/overweight adolescents. According to one systematic review, lack of access to transportation was reported in five different studies of obese youth as a contributor to drop-out.²⁵

The other factor contributing to program non-completion is older age. This has been found to be associated with drop-out and non-adherence in the literature.^{23,27} For example, in a study of 183 obese and overweight adolescents participating in a multidisciplinary, community-based weight loss program, those aged younger than 15 years were 60% less likely to drop out of the program.²³ In a 2004 study of 212 obese youths participating in a clinical program, only 45% completed and older participants were 64% more likely to drop out of the program.²⁷

Altogether, HKI had high rates of completion with positive improvements in health, mental health and well-being. The program's requirement of a buddy, three signed social support contracts, and cognitive behavior education, are all critical elements of the program. Social support has been found to be an important part of maintaining physical activity changes in adults, but there is little literature that assesses this directly in youth participating in weight reduction or behavioral modification interventions. Although many programs adopt group-based strategies (as per recommendations),¹¹ few studies appear to assess this directly. One study found that having friends and peers present while engaging in physical activity motivated obese boys.²⁸ Additionally, among obese youth, perception of better peer support is associated with higher HRQoL.²⁹

Limitations

The study design was a prospective longitudinal cohort and not a randomized controlled trial (RCT). After

Table 6 Percentage of HKI Participants Across Three Levels of Depressed Mood Symptomatology at Baseline Compared to 12-Week Completion

Depressed Mood Levels		Baseline n (%)		12-Week n (%)	
No depressed mood		29 (1.6)		128 (7.2)	
Somewhat elevated depressed mood		680 (38)		1239 (69.3)	
Very elevated depressed mood		1080 (60.4)		422 (23.6)	
Depressed Mood (CES-D 12)	Baseline Mean (SD)	12-week Mean (SD)	Absolute Change	% Change	p-value
Overall	21.47 (5.36)	17.40 (4.36)	-4.07	19%	<0.001

community consultation, it was clear that an RCT study design would not be supported. As well, after community consultation, it was clear that a control group without intervention would not be supported. This is another limitation of our study. However, the lack of use of an RCT means that the findings are associations, and cannot be thought of as implying causation. The study does have a 12-month long-term follow-up but those results are not available yet.

Conclusion

The HKI is a community-based initiative targeting behavior modification for overweight and obese youth with a high completion rate and early success in improving health, mental health and behavioral outcomes. Knowing the risk factors for non-completion of the first five waves will allow for program modification to target at-risk participants to help complete the program.

Patient Preference and Adherence

Dovepress

Publish your work in this journal

Patient Preference and Adherence is an international, peer-reviewed, open access journal that focusing on the growing importance of patient preference and adherence throughout the therapeutic continuum. Patient satisfaction, acceptability, quality of life, compliance, persistence and their role in developing new therapeutic modalities and compounds to optimize clinical outcomes for existing disease

states are major areas of interest for the journal. This journal has been accepted for indexing on PubMed Central. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
