Objective: To determine the clinical and economic consequences of inhaled corticosteroid doses and particle size in patients on triple-inhalation therapy for COPD.

Methods: Patients aged ≥ 40 years who initiated treatment with multi-inhaler triple-inhaled therapy between 1 January 2015 and 31 March were included and followed for 1 year. Patients were grouped according to inhaled corticosteroid (ICS) dose (low/medium/high) and particle size device (extrafine/non-extrafine particles). Outcome variables were moderate and severe exacerbations, pneumonia and healthcare resource use (HCRU) costs. A multivariate analysis was performed for model correction ($p < 0.05$).

Results: A total of 2185 patients (mean age 72.3 years, 82.9% male) were analysed. Of these, 849 (38.9%) patients received low-dose ICS, 612 medium-dose ICS (28.0%) and 724 (33.1%) high-dose ICS. Exacerbations occurred more frequently with increasing IC dose (low: 26.4%, medium: 28.7% and high: 30.4%; $p = 0.047$), as did the proportion of pneumonia (3.4%, 4.2% and 6.9%, respectively ($p = 0.041$)). The annual mean cost/unit was € 2383 for low dose, € 2401 for medium dose and € 2625 for high dose ($p = 0.024$). Four hundred and sixty-two (31.6%) patients used an extrafine particle device and 999 (68.4%) a non-extrafine particle device: the proportion of exacerbations was 24.0% vs 30.4% ($p = 0.012$), and the annual mean cost/unit was € 2090 vs € 2513, respectively ($p < 0.001$). The number of exacerbations was directly correlated with FEV₁ ($\beta = -0.157$), age ($\beta = 0.071$), Charlson index ($\beta = 0.050$) and device type (extrafine: $\beta = 0.049$) ($p < 0.02$).

Conclusion: In patients with COPD receiving multi-inhaler triple therapy, higher ICS doses were not associated with a further reduction in exacerbations, whereas we found an increased risk of pneumonia. The use of inhaler devices delivering extrafine ICS particle was associated with a lower rate of exacerbations, resulting in lower overall HCRU costs.

Keywords: COPD, triple-therapy, extrafine particle, exacerbations, pneumonia, health costs

Introduction

Chronic obstructive pulmonary disease (COPD) is characterized by progressive, difficult-to-reverse, chronic limitation of the airflow¹ that is associated with an abnormal inflammatory lung response to harmful particles or gases, especially tobacco, with significant systemic repercussions.^{1,2} Around the world, COPD is an increasingly prevalent disease,^{3,4} with a prevalence of 6–10.4% estimated in Spain, among people aged 40–80 years.⁴ COPD is a public health problem as it is the fourth leading cause of death worldwide, and one of the leading causes of morbidity, occupational disability, and worsened quality of life.^{1,2} COPD results in

high healthcare costs, with the most severe patients and COPD exacerbations consuming the most resources.^{1–3} In Spain, the direct mean cost per patient with COPD is estimated at €1712–3238/year, 50–70% of which are in hospital costs.^{5–7}

Maintenance pharmacotherapy for COPD is based on long-acting bronchodilators as the first line of treatment with long-acting beta adrenergic [LABA] and/or long-acting anticholinergics [LAMA]. LABA in combination with inhaled corticosteroid (ICS) is reserved for patients with frequent exacerbations and/or a mixed COPD-asthma phenotype, regardless of the level of functional severity,^{1,8,9} and triple therapy with LAMA-LABA-ICS can be a potentially effective treatment in this group of patients as well.^{2,9} The TRILOGY¹⁰ and FULFIL¹¹ clinical trials highlighted the superiority of the combination of the three drugs in patients with severe COPD over the use of IC/LABA alone. In clinical practice, the use of ICS in COPD is controversial (balance between efficacy and safety [pneumonia]), with arguments both for and against their use, and only in combination with an LABD.¹² The WISDOM study^{13,14} found no increased risk of adverse effects in triple therapy compared with dual bronchodilation (LABA/LAMA). However, the benefit–risk ratio of ICS-containing therapy may depend on several factors, including the ICS molecule characteristics (potency, lipophilicity), dose, and particle size.^{9,12} There seems to be some consensus on the use of medium-low dose ICS in patients with the COPD-asthma phenotype and in frequent exacerbators.¹²

Particle size is the major determinant in the deposition and distribution of inhaled drug within the lungs and hence is related to local efficacy. The particle size distribution of an aerosol is usually expressed in terms of its mass median aerodynamic diameter (MMAD). To reach the lower respiratory tract past the carina, the MMAD of inhaled particles should be less than 5 µm in diameter; specifically, the particle size with the most efficient deposition in the small airways, so-called extrafine particle fraction, is said to be less than 2 µm.¹⁵ The literature reviewed does not usually differentiate between the type of particles (extrafine vs non-extrafine/fine) contained in inhalers used for treating COPD.¹⁶ While most ICS are fine particles with an MMAD of 2–4 microns, some presentations use extrafine particles (approximate diameter of 1 micron). Some authors suggest there may be better effectiveness and clinical safety with the use of extrafine particle devices for the treatment of COPD,^{17,18} but there is very little data on their impact in normal clinical

practice. In addition, evidence on the healthcare resource use and associated costs in this patient group is limited. The objective of the study was to determine the clinical (exacerbations and pneumonia) and economic consequences (healthcare resource use and costs) of the use of different doses of inhaled corticosteroids (high/medium/low) and their particle size (extrafine vs non-extrafine) in multi-inhaler triple inhalation therapy for COPD.

Patients and Methods

Design and Study Population

An observational, multicentre, longitudinal retrospective study was carried out using a before/after design with a control group, made by review of computerized medical records. The study population was obtained from the records of health providers from various centres in Spain (unified in the dissociated BIG-PAC[®] database; Real Life Data; <http://www.encepp.eu/encepp/search.htm>). The medical records come from different primary care centers and hospitals (integrated areas) from seven Autonomous Communities of the Spanish territory (computerized medical records, 1.9 million patients). Data are subject to rigorous validation and recoding (anonymized/dissociated data) and are then exported to the BIG-PAC[®] database. The population assigned to the participating centres is mostly urban with medium-low socioeconomic status.

Inclusion and Exclusion Criteria

Patients who sought care and initiated treatment with multi-inhaler triple therapy (LAMA-LABA-ICS) between 1 January 2015 and 31 March 2017 were included in the study. Inclusion criteria were: (a) age ≥40 years, (b) date of diagnosis of COPD ≥ 12 months before the index date, (c) inclusion in the prescription programme for obtaining medical prescriptions (with a recorded daily dose, time interval and duration of each treatment administered, and two or more prescriptions), (d) guaranteed regular monitoring (two health records in the computer system) and (e) ≥6 months on treatment with triple therapy. Exclusion criteria were (a) transfer out to other centres, displaced or out-of-area, (b) permanent institutionalization, and (c) a history of pulmonary emphysema, bronchiectasis, cystic fibrosis and/or bronchial neoplasm.

Study Groups and Follow-Up Period

Patients were differentiated according to: 1) ICS dose: a) low dose, b) medium dose and c) high dose; and 2) ICS

particle size: a) extrafine particle (EFP) (Modulite[®], NextHaler[®]) and b) non-extrafine particle (nEFP). Patients were classified in ICS dose groups following the Bassan¹⁸ criteria according to the initial prescription regimen ([Supplementary Table 2](#)). The follow-up period was 1 year from the index date. Analysis of the ICS-containing inhalers excluded patients receiving high doses of ICS (N=724), as patients were not receiving high doses of ICS in extrafine particle devices for comparison.¹⁸

Definition of COPD, Exacerbation, and Pneumonia

Records of patients with COPD were obtained using the International Classification of Diseases (ninth edition) Clinical Modification (ICD-9-MC; codes 491, 492 and/or 496 for COPD and/or exacerbations) or their ICD-10 equivalents (codes: J41, J42, J44). The physician's judgement was the criteria followed. However, confirmation of the COPD diagnosis required the recording of no significant reversibility airflow obstruction following bronchodilator administration according to forced spirometry and the forced volume in the first second (FEV₁/forced vital capacity ratio < 70% in the stable phase). The Global Initiative for Obstructive Lung Disease (GOLD)⁸ guidelines, which define an exacerbation as an event in the natural course of the disease characterized by a change in patient's baseline dyspnoea, cough and/or sputum that goes beyond daily variations, which is acute in its onset, and may require a change in regular medication (sustained aggravation of the baseline situation). In this respect, two types of exacerbations were considered: (a) severe: those requiring hospital admission, and (b) moderate: those requiring treatment with antibiotics and/or oral corticosteroids. For each exacerbation, blood eosinophil levels and the time from diagnosis (in years) were obtained. In addition, lung function (FEV₁) and the functional severity of COPD (classification) were also obtained according to GOLD⁸ recommendations. Additionally, the records of patients with pneumonia were obtained using ICD-9-MC; codes 482–486, or their equivalents, according to ICD10: J12–J18.

Sociodemographic and Comorbidity Variables

Sociodemographic and comorbidity variables recorded were age (continuous and by intervals), sex, and the history of hypertension, diabetes, dyslipidaemia, obesity (BMI 30 kg/m²), active smoking, ischemic heart disease,

stroke, heart failure and other conditions ([Table 1](#)). As a summary variable of general comorbidity, a) the Charlson comorbidity index¹⁹ and b) the number of chronic comorbidities were collected for each patient.

Description of Treatment

The medications indicated for the treatment of COPD were obtained according to the Anatomical Therapeutic Chemical Classification System (ATC):²⁰ oral corticosteroids (OCS, H02AB), IC/LABA (R03AK), beta-2 short-acting agonists (SABA, R03AC), short-acting muscarinic antagonist or anticholinergics (SAMA, R03BB), LAMA (R03BB), xanthines (R03DA and R03DB), leukotriene receptor antagonists (R03DC), and home oxygen. In addition, patients who received treatment with long-acting oral/systemic corticosteroids (chronic schedule) were differentiated from those who received them only for the control of an exacerbation. The duration of ICS treatment was calculated as the difference in dates between the initial prescription (index date) and the final prescription (last available prescription), in months (during the follow-up period). In addition, a treatment change was considered when there was a modification of any of the three molecules (ICS, LAMA, LABA), with respect to the baseline situation. A change in treatment was not considered when there was a variation in the dose or the type of device used.

Healthcare Resource Use

Direct health costs related to care (medical visits, days of hospitalization, emergency visits, diagnostic or therapeutic requests and medication) provided by professionals were collected. Costs were expressed at the mean cost per patient per year (mean PPY). The study concepts and their costs in € 2018 are shown in [Supplementary Table 1](#). The cost of prescriptions for each medication was quantified according to the retail price per pack at the time of prescription.

Ethical and Legal Aspects

Clinical records in the BIG-PAC database are fully anonymised, and researchers do not have access to patients' personal data. When the information used does not contain personal data, Spanish law exempts studies from evaluation by a Research Ethics Committee.

Statistical Analysis

Data were validated to ensure the quality of the records. A descriptive-univariate statistical analysis was made.

Qualitative data were expressed as absolute and relative frequencies and quantitative data as means and standard deviation or medians and interquartile ranges. The 95% confidence intervals (CI) used to estimate parameters were based on the total number of subjects without missing values. The normality of distribution was tested using the Kolmogorov–

Smirnov test. In the bivariate analysis, ANOVA, the chi-square and Pearson's linear correlation tests were used.

The multivariate models used were (a) covariance analysis (ANCOVA; procedure: estimation of marginal means; Bonferroni's adjustment) for correction of resource use (dependent variable, according to patient classification),

and (b) multiple linear regression to determine variables associated with health costs and exacerbations (procedure: consecutive steps). The covariates included in the models were age, sex, FEV₁, the Charlson index and time from diagnosis. Statistical significance was established as $p < 0.05$. The analysis was made using SPSSWIN version 23.

Results

Of an initial population of 1.9 million, 802,237 patients aged ≥ 40 years received care between 1 January 2015 and 31 March 2017. Of these, 13,690 patients were diagnosed with COPD. Finally, 2185 patients who met the inclusion/exclusion criteria were analysed and followed during the study period (Figure 1).

Results According to ICS Dose

Table 1 shows the general characteristics of patients according to study groups: 849 patients received low-dose ICS (38.9%), 612 received medium-dose ICS (28.0%) and 724 received high-dose ICS (33.1%). The distribution of ICS dose according to the different drug combinations (number of patients) is detailed in Supplementary Table S3. The mean age was 72.3 years and 81.1% were male. Hypertension (61.1%), dyslipidaemia (54%), obesity (33.7%) and diabetes (27%) were the most frequent comorbidities. There was acceptable comparability between the ICS dose groups with respect to sociodemographic characteristics and associated comorbidities.

Table 2 shows the main complications (exacerbations and pneumonia) according to the ICS dose. Total exacerbations increased from baseline with increasing dose of ICS (low: 26.4%, medium: 28.7% and high: 30.4% ($p=0.047$)). Both moderate (26.2%, 28.9% and 29.1% ($p=0.044$)) and severe exacerbations (6.7%, 9.2% and 11.2% ($p=0.014$)) were higher in patients on high-dose IC. The mean time to first exacerbation was significantly shorter in patients taking high doses of ICS (132, 130 and 116 days, respectively ($p < 0.05$)) (Table 2). Significant associations were also observed between high doses and the functional severity of COPD (in severe COPD; low: 34%, medium: 37.2%, and high: 42.8% ($p=0.029$)), as well as between ICS dose and use of oral corticosteroids (low: 21.8%, medium: 23.5% and high: 26.4% ($p < 0.001$)) and % FEV₁ (low: 60.7%; medium: 58.6% and high: 54.9% ($p < 0.001$)) (Table 2).

The proportion of pneumonia (patients) increased with the ICS dose (low: 3.4%, medium: 4.2% and high: 6.9% ($p=0.041$)). Total healthcare costs were € 5.3 million, of which 66.1% were in primary healthcare and 33.9% in specialized care. The biggest cost components were hospital admissions (9.8%), primary healthcare visits (14%) and medication (48.7%). The annual mean PPPY cost (corrected for covariates, ANCOVA) was higher with increasing dose of ICS (low: € 2383, medium: € 2401 and high: € 2625 ($p=0.024$)) (difference between high-/low-dose ICS: € 242/patient/year) (Table 3).

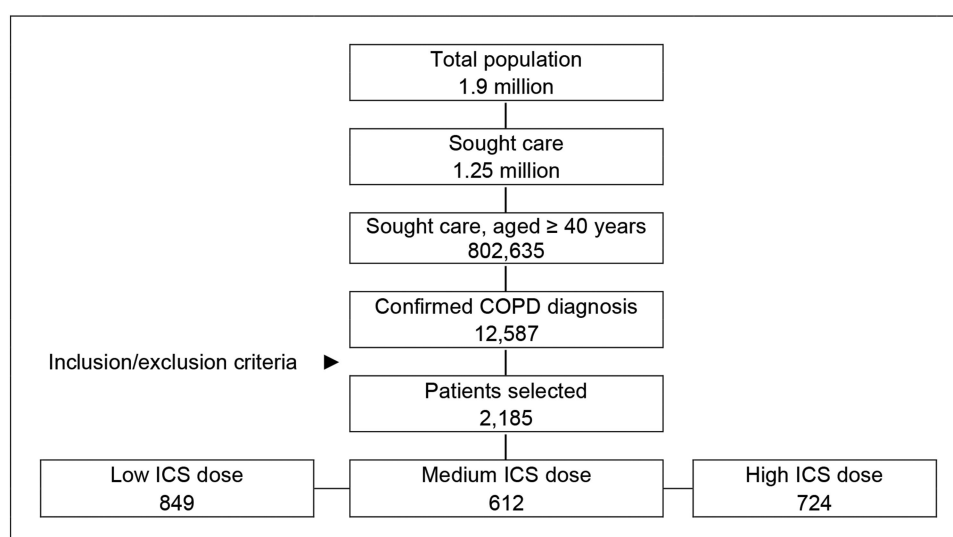

Figure 1 Study flow diagram. A retrospective observational study was carried out, made from the review of medical records (computerized databases, with anonymised and dissociated data) of patients diagnosed with COPD.

Abbreviation: ICS, inhaled corticosteroid.

Results According to ICS Particle Size

Table 4 shows general patient characteristics according to the particle size (subjects with high doses of ICS were excluded): 462 patients (31.6%) received treatment with an EFP ICS/LABA, and 999 with an nEFP ICS/LABA (68.4%). In general, the baseline characteristics were comparable between the groups analysed. Patients using EFP, compared with nEFP, had similar functional COPD severity (GOLD III: 37% vs 36.4%; $p=0.861$), oral

corticosteroid use (26.4% vs 25.3%, $p=0.413$) and FEV₁ (59.3% vs 60.1%; $p=0.269$).

Table 5 shows the proportion of exacerbations and pneumonia according to the ICS particle size. Total exacerbations were lower for EFP vs nEFP (24% vs 30.4%; $p=0.012$). Moderate exacerbations were also lower for EFP vs nEFP (23.6% vs 29.9%; $p=0.048$), while serious exacerbations (hospital admissions: 6.5% vs 8.3%; $p=0.078$) did not differ significantly. No relevant

differences were found according to ICS duration or treatment changes (ICS, LABA, LAMA) across the different cohorts analyzed, during the follow-up period (Tables 1 and 5). The incidence of pneumonia was similar between the two groups (3% vs.4.3%; $p=0.378$). For nEFP, the median time to first exacerbation was faster than for EFP (126 vs.160 days ($p=0.004$)). The annual mean PPPY healthcare cost with an EFP ICS was lower than that on nEFP ICS (€ 2090 vs € 2, 513 ($p<0.00$)) (difference: € -423/patient/year) (Table 6).

Joint Analysis

In the binary correlation model, age was principally associated with the time from diagnosis ($r=0.332$), comorbidity ($r=0.338$), mortality ($r=0.258$) and exacerbations

($r=0.177$). Comorbidity was associated with healthcare costs ($r=0.162$), exacerbations ($r=0.138$) and pneumonia ($r=0.075$). High doses of ICS were associated with FEV₁ ($r=0.178$), and healthcare costs with exacerbations ($r=0.792$) and pneumonia ($r=0.145$). nEFP ICS were associated with the number of exacerbations ($r=0.077$) and healthcare costs ($r=0.154$) ($p<0.03$). In the multiple linear regression analysis, healthcare costs were associated with the number of exacerbations ($\beta=0.807$), age ($\beta=0.178$), ICS particle size (nEFP: $\beta=0.121$), high doses of ICS ($\beta=0.042$), comorbidity ($\beta=0.041$) and FEV₁ ($\beta=-0.024$) ($p<0.02$ in all cases). The model determination coefficient was 65.2%. The number of exacerbations (during follow-up) was associated with FEV₁ ($\beta=-0.157$), age ($\beta=0.071$), comorbidity (Charlson: $\beta=0.050$) and ICS particle size

(nEFP: $\beta=0.049$) ($p<0.02$). The model determination coefficient was 40.1%.

Discussion

The results of this study show that, in patients beginning triple therapy, an increase in the IC dose was not associated with a reduction in the number of exacerbations, while an increased risk of pneumonia was observed. Likewise, with equal severity of COPD, patients treated with EFP had lower rates of severe and moderate

4.2% and 6.9%, respectively). The combination of IC + LAMA/LABA is controversial in the treatment of COPD.^{1,2,9,12} Some reviews show that triple therapy provides modest clinical benefits in the general COPD population, while achieving greater efficacy in patients with frequent exacerbations and eosinophilia (asthma-COPD phenotype).^{12,21,22} Conversely, adding a LAMA to an IC/LABA combination produces significant clinical benefits in COPD patients (dual bronchodilation).^{21,22} Most studies highlight the discrepancies between the guideline recommendations and the therapy used in clinical practice.^{9,12,21,22}

There is debate on the side effects, such as pneumonia and systemic adverse effects, of long-term IC use. Some reports suggest the safety profile of IC depends on the dose administered. Thus, there appear to be differences between the pathophysiological mechanisms related to the action of

IC, which are predominantly immunosuppressant at high doses and anti-inflammatory at lower doses. This may have practical effects, highlighting the value of low-dose IC in the treatment of COPD.²³ We found that patients who received high doses of IC vs low/moderate doses showed no reduction in exacerbations, although previous exacerbations were not considered, and these patients had more severe COPD. These results show the complexity of COPD therapy, especially in severe patients. As for the risk of pneumonia, our results seem to be in line with most studies, although this topic is also controversial. Cheng²⁴ concluded that high doses of IC had greater clinical effectiveness in COPD patients, with no higher incidence of pneumonia, and suggest that high-dose IC therapy may be appropriate in COPD patients. The Spanish PNEUMOCORT²⁵ study found that severe pneumonia and exacerbations were more common in patients with severe COPD and in patients receiving high doses of IC, results similar to ours.

The proportion of exacerbations was 24% in patients using EFP devices and 30.4% in those using nEFP devices. In the joint analysis (IC dose vs device type), exacerbations were indirectly related to the use of EFP devices (corrected by covariates). There is little reported evidence, but the TRILOGY¹⁰ and TRINITY²⁶ studies permit assessment of the effectiveness and safety of devices with EFP compared with other types of devices. Both studies show a slight reduction in exacerbations and the risk of pneumonia. The FORWARD²⁷ and TRIBUTE²⁸ studies also found a reduction in exacerbations, but no increase in the risk of pneumonia. A review by Scichilone²⁹ found that an inability to reach and treat peripheral airways may contribute to a lack of efficacy of inhaled treatments. The development of extrafine inhaled formulations allows a more uniform distribution of inhaled treatment throughout the respiratory tree. Better knowledge of the pathophysiology of the peripheral airways may help identify specific COPD phenotypes that would benefit from these treatments. Despite methodological discrepancies, our results may be in line with these contributions.

The mean cost per patient/year was higher in patients receiving high doses of IC compared with medium and low doses (€ 2625, € 2383 and € 2401, respectively). Likewise, costs were lower in patients with EFP devices (€ 2090) than in those using nEFP devices (€ 2513). These results are directly related to the proportion of exacerbations, especially severe exacerbations requiring hospitalization. Reviews by Press³⁰ and Ehteshami-Afshar³¹ highlighted

the wide methodological differences in the studies analysed and concluded that reports consistently show that better disease control reduces COPD costs and that there is a growing need for economic studies based on the latest guideline recommendations. Our results are difficult to compare since we have found no similar studies in the literature search. Most studies conclude that: a) the cost is related to COPD severity, b) rehospitalizations, emergency visits and medication were the most prominent cost components, and c) increasing health education can reduce COPD costs.^{32,33} In addition, COPD patients with eosinophil counts of ≥ 220 cells/ μ L are more likely to have had moderate or severe exacerbations, implying higher costs.³⁴ Allowing for methodological limitations, our results seem to be in line with the available literature.

Our study has some limitations, principally those typical of retrospective studies, which are related to the categorization of COPD severity, the possible classification bias of patients and the limitations in the measurement of variables, attributable to the information system. In this respect, the possible inaccuracy of diagnostic coding in the diagnosis of COPD and other comorbidities, the definition of exacerbation, or the absence of variables that could influence the final results (socioeconomic level, environmental/occupational exposure, evolution of the pharmacological dose prescribed, verification of the inhalation technique, therapeutic adherence and/or the differentiation of phenotypes), should be considered as limitations. Other unmeasured factors that might have influenced the results may include: a) the length of use of IC in triple therapy, b) the pharmacological characteristics of the drug combinations, and/or c) the combination of these in each device (IC/LAMA/LABA, IC/LABA + LAMA, LABA/LAMA + IC). In addition, based on the demand for medical care, non-disease factors may have influenced the results, such as access to health resources, comorbidity or patient specifics, which could cause worsening episodes not to be reported by the patient and therefore remain untreated. We cannot exclude an indication bias due to severity, but when we adjust for parameters related with severity it does not seem to be any relevant difference. Regarding the changes in medication, the modifications of the concomitant respiratory treatment were not considered either, due to the technical complexity (time period) that represented their quantification in the database. Unfortunately, a more detailed analysis by molecules was not possible due to the small sample size. However, this study reflects routine clinical practice, in which the degree of adherence to clinical practice guidelines is rather low. In fact, in clinical practice it is common that more than 50% of patients are taking the high

dose triple in GOLD, which is not in accordance with the (GOLD) guidelines.³⁵

In conclusion, triple therapy may be an appropriate option in many patients, with low doses of IC. Increased IC doses were not associated with a reduction in the number of exacerbations, while an increased risk of pneumonia was observed. Patients treated with extrafine particle devices had lower rates of severe and moderate exacerbations, resulting in lower health costs for the Spanish National Health System. These results should be replicated in other healthcare settings.

International Journal of Chronic Obstructive Pulmonary Disease**Dovepress****Publish your work in this journal**

The International Journal of COPD is an international, peer-reviewed journal of therapeutics and pharmacology focusing on concise rapid reporting of clinical studies and reviews in COPD. Special focus is given to the pathophysiological processes underlying the disease, intervention programs, patient focused education, and self management

protocols. This journal is indexed on PubMed Central, MedLine and CAS. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
