Background: Cervical cancer belongs to one of the most common female cancers; yet, the exact underlying mechanisms are still elusive. Recently, microarray and sequencing technologies have been widely used for screening biomarkers and molecular mechanism discovery in cancer studies. In this study, we aimed to analyse the microarray datasets using comprehensive bioinformatics tools and identified novel biomarkers associated with the prognosis of patients with cervical cancer.

Methods: The differentially expressed genes (DEGs) from Gene Expression Omnibus (GEO) datasets including GSE138080, GSE113942 and GSE63514 were analysed using GEO2R tool. The functional enrichment analysis was performed using g:Profiler tool. The protein-protein interaction (PPI) network construction and hub genes identification were performed using the STRING database and Cytoscape software, respectively. The hub genes were subjected to expression and survival analysis in the cervical cancer. The EdU incorporation and Cell Counting Kit-8 assays were performed to evaluate the effects of hub gene knockdown on the proliferation of cervical cancer cells.

Results: A total of 89 overlapping DEGs (63 up-regulated and 26 down-regulated genes) were identified in the microarray datasets. The functional enrichment analysis indicated that the overlapping DEGs were mainly associated with "DNA replication" and "cell cycle". Furthermore, the PPI network analysis revealed that the network contains 87 nodes and 309 edges. Sub-module analysis using the Molecular Complex Detection tool identified 21 hub genes from the PPI network. The expression levels of the 21 hub genes were all up-regulated in the cervical cancer tissues when compared to normal cervical tissues as analysed by GEPIA tool. The survival analysis showed that the low expression of cell division cycle 45 (*CDC45*), GINS complex subunit 2 (*GINS2*), minichromosome maintenance complex component 2 (*MCM2*) and proliferating cell nuclear antigen (*PCNA*) was significantly correlated with the shorter overall survival of patients with cervical cancer. Moreover, the protein expression levels of *GINS2*, *MCM2* and *PCNA*, but not *CDC45*, were significantly up-regulated in the cervical cancer tissues when compared to normal cervical tissues. Finally, knockdown of *MCM2* significantly suppressed the proliferation of HeLa and SiHa cells.

Conclusion: In conclusion, we screened a total of 89 overlapping DEGs from the GEO datasets, and further analysis identified four hub genes (*CDC45*, *GINS2*, *MCM2* and *PCNA*) that were likely associated with the prognosis of patients with cervical cancer. *MCM2* knockdown repressed the cervical cancer cell proliferation. The current findings may provide novel insights into understanding the pathophysiology of cervical cancer and develop therapeutic targets for patients with cervical cancer.

Introduction

Cervical cancer belongs to one of the most common female cancers, and persistent infection of high-risk human papillomavirus is one of the major causal factors for the development of cervical cancer.¹ In 2019, there were more than 500,000 new cases and 300,000 deaths globally, with about 90% of cases occurring in low-income areas.² Though vaccination and routine physical examination have been effective in preventing the development of cervical cancer, the mortality of cervical cancer is still high particularly in low-income areas.² The high mortality of cervical cancer is mainly due to the lack of early diagnosis, as the patients with advanced cervical cancer miss the opportunity for surgeries and are often resistant to radio/chemotherapy.^{3–5} Great efforts have been invested to uncover the pathophysiology of cervical cancer, however, the exact underlying mechanisms are still elusive, which requires further exploration.

High throughput technology has been a powerful tool to study the human genomics. Recently, microarray and sequencing technologies have been widely used for screening biomarkers and molecular mechanism discovery in cancer studies.^{6,7} The analysis of multi-omics databases like the Gene Expression Omnibus (GEO) as well as The Cancer Genome Atlas (TCGA) makes it possible to access microarray data and compare cancer profiles to normal profiles.^{8,9} In the cervical cancer studies, the bioinformatics analysis has been employed to identify the biomarkers and signalling pathways associated with the pathophysiology of cervical cancer. Dai et al, performed the integrated bioinformatics analysis from GEO datasets and identified that the lower expression of Krüppel-like factor 4 and estrogen receptor 1 was closely correlated with the poor prognosis of patients with cervical cancer.¹⁰ Liang et al, showed that three microRNA's (miR-145, miR-200c and miR-281-1) signatures predicted survival in cervical cancer using bioinformatics analysis.¹¹ Lin et al, performed genome-wide analysis of aberrant gene expression and methylation profiles and indicated that endothelin-3 and endothelin receptor B might play important roles in the progression of cervical cancer, and LIM homeobox 2, acyl-coenzyme A oxidase 3, cytochrome P450 family 39 subfamily A member 1 and dihydropyrimidinase might be susceptible genes and potential risk markers in cervical cancer.¹² To date, the public microarray datasets regarding cervical cancer are still not fully explored, and further analysis of these microarray

datasets may be helpful for us to identify novel biomarkers associated with cervical cancer progression.

In this study, we integrated three microarray datasets including GSE138080, GSE113942 and GSE63514 from the GEO database and screened the differentially expressed genes (DEGs) from these datasets. The functional enrichment analysis was performed to annotate these DEGs. Protein-protein interaction (PPI) network analysis of the DEGs was performed to identify the hub genes. Moreover, the expression and survival analysis of the hub genes were further analysed using the online databases, which may provide novel insights into understanding the prognostic role of the identified hub genes in cervical cancer. Finally, the biological role of the hub gene (*MCM2*) in the cervical cancer cells was validated by in vitro functional assays.

Materials and Methods

Microarray Data Collection

By searching the GEO database using “cervical cancer” as the keywords, three microarray datasets including GSE138080, GSE113942 and GSE63514 were downloaded for analysis in this study. The platform for GSE138080 is GPL4133, Agilent-014850 Whole Human Genome Microarray 4x44K G4112F (Feature Number version), which contains 10 normal cervical samples and 10 cervical cancer specimens; the platform for GSE9750 is GPL96, [HG-U133A] Affymetrix Human Genome U133A Array, which contains 22 normal cervical samples and 33 cervical cancer tissues; the platform for GSE63514 is the GPL570 [HG-U133_Plus_2] Affymetrix Human Genome U133 Plus 2.0 Array, which contains 24 normal cervical epithelial tissues and 28 cervical cancer tissues.

Identification of DEGs from GEO

Datasets

GEO2R (<https://www.ncbi.nlm.nih.gov/geo/geo2r/?acc=GSE40435>) was used to compare gene expression profiles between normal cervical tissues and cervical cancer tissues. The Benjamini-Hochberg method was used to determine the false discovery rate and the adjusted *P*-value was used to reduce the likelihood of false positive errors. The selection criteria for the DEGs was based on an adjusted *P*-value of < 0.05 and |log fold change (FC)| ≥ 1.5. Finally, the overlapping DEGs among the three datasets was identified by a Venn diagram tool.¹³

Functional Enrichment Analysis

Gene ontology (GO) analyses focuses on three domains: biological processes, cellular components, and molecular functions, and such analyses are used to understand the biological functions, pathways, or localization of DEGs. The Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway analysis database serves as a valuable resource for assessing how particular DEGs may be involved in or influenced by specific signalling pathways and disease states. The g: Profiler tool was utilized for functional enrichment analyses, with a $P < 0.05$ cut-off for significance.¹⁴

PPI Network of DEGs

The PPI network of the overlapping DEGs was analysed using the STRING database (<http://www.bork.embl-heidelberg.de/STRING/>),¹⁵ which is a computerized and powerful global resource for studying the interactions between the predicted and experimental interactions of proteins. A combined score of ≥ 0.7 was used as the cut-off value. A Molecular Complex Detection (MCODE) plug-in in Cytoscape (version 3.6.1) was used to select the PPI network modules, with a cutoff = 2, node score cutoff = 0.2, k-core = 2 and maximum depth = 100 as the selection criteria. The hub genes were then extracted from the PPI network modules.

Expression Analysis of Hub Genes in Cervical Cancer

The expression analysis of hub genes in cervical cancer was performed using the Gene Expression Profiling Interactive Analysis (GEPIA) tool,¹⁶ which is a new web-based tool that uses standardized, integrated processing to analyse tumor and normal gene expression from The Cancer Genome Atlas (TCGA) and genotype tissue expression (GTEx) and contains 319 cervical tissue samples (306 tumor samples and 13 normal tissue samples) from the TCGA database, and the differential expression of the hub genes was defined when $P < 0.01$. The protein expression of hub genes in the cervical tissue was obtained from the online database (Human Protein Atlas database, <https://www.proteinatlas.org/>).

Survival Analysis of Hub Genes in Cervical Cancer

The overall survival analysis of the hub genes in cervical cancer was analysed by the GEPIA tool, Human Protein

Atlas database (<https://www.proteinatlas.org/>) and KM plotter (<https://kmplot.com/analysis/index.php?p=background>),¹⁷ respectively. The GEPIA database contains survival data of 292 patients with cervical cancer. The Human Protein Atlas database includes survival data of 291 patients with cervical cancer. The KM plotter database contains survival data of 304 patients with cervical cancer. Log rank $P < 0.05$ was considered to be statistically significant.

Cell Culture

Two human cervical cancer cell lines (HeLa and SiHa) were obtained from ATCC (ATCC, USA). HeLa and SiHa cells were cultured in DMEM medium supplemented with 10% fetal bovine serum (FBS, Thermo Fisher Scientific, USA) in a humidified atmosphere with 5% CO₂ at 37 °C.

Quantitative Real-Time PCR (qRT-PCR)

Cervical cancer cells were collected at 24 h after siRNA transfection for RNA extraction. Total RNA was reverse transcribed to cDNA using a First Strand cDNA kit (TaKaRa, Japan). qRT-PCR was performed by using SYBR Green PCR Master Mix (Applied Biosystems, USA). *GAPDH* was used as the endogenous control for mRNA expression. Relative gene expression levels were determined by the Ct method. The primers were as follow: *MCM2*, forward: 5'-TGCCACTGTATCCTAGCCA-3' and reverse: 5'-GATGGAAGGAGCAATGCTGG-3'; *GADPH*, forward: 5'-5'-GCAAATTCATGGCACCCT-3' and reverse: 5'-TCGCCCCACTTGATTTTGG-3'.

Small Interfering RNA (siRNA) and Cell Transfection

HeLa and SiHa cells were transfected with siRNAs against *MCM2* (si*MCM2*) or scrambled siRNA (siNC) by using Lipofectamine 3000 (Thermo Fisher Scientific), when HeLa and SiHa cells were up to ~80% confluence. The *MCM2* siRNA sequence was 5'-GGAGCUCAUUGGAGAUGGCAUGGAA-3'.

EdU Incorporation Assay

The EdU incorporation assay was performed using an EdU DNA Cell Proliferation Kit (RiboBio, Guangzhou, China) to detect cell proliferation by following the manufacturer's protocol. The number of EdU-positive cells was counted in 6 randomly selected fields.

Cell Counting Kit-8 (CCK-8) Assay

Cell proliferation was evaluated by CCK-8 assay (Dojindo, Tokyo, Japan). Briefly, the transfected HeLa and SiHa cells were seeded into 96-well plates. At indicated time points, 10 μ L of CCK-8 solution was added to each well followed by incubation at 37 °C for another 2 h. The cell proliferative index was measured by detecting the absorbance at 450 nm using an automatic spectrophotometer.

Statistical Analysis

All analyses were performed using GraphPad Prism version 6.0 (GraphPad Software, USA). Data are expressed as the mean $\pm$ standard deviation, and differences between groups were analysed by one-way ANOVA followed by Bonferroni's multiple comparison tests. Statistical significance was set at $P < 0.05$.

Results

Screening of DEGs from GEO Datasets Including GSE138080, GSE113942 and GSE63514

The workflow of our bioinformatics analysis and experimental validation is shown in [Figure 1](#). We screened the DEGs from three datasets including GSE138080, GSE113942 and GSE63514, and presented the DEGs in each dataset using the volcano plots ([Figure 2A–C](#)). Pink and blue dots represented the up-regulated and down-regulated genes, respectively. In the GSE138080, a total of 813 DEGs with 308 up-regulated and 505 down-regulated genes were identified; in the GSE113942, a total of 3370 DEGs with 2079 up-regulated and 1291 down-regulated genes were identified; in the GSE63514, a total of 3023 DEGs with 1897 up-regulated and 1126 down-regulated genes were identified. The overlapping DEGs were identified in the up-regulated and down-regulated genes. As illustrated by the Venn diagrams, a total of 89 overlapping DEGs with 63 up-regulated and 26 down-regulated genes were identified among these datasets ([Figure 2D](#); [Supplemental Table 1](#)).

Functional Enrichment Analysis of Overlapping DEGs

The 89 overlapping DEGs were firstly subjected to the GO enrichment analysis. The top 10 enriched GO terms from biological process, cellular component and molecular

Figure 1 Workflow of the bioinformatics analysis and experimental validation.

function are shown in [Figure 3A–C](#). In the biological process, the DEGs were significantly enriched in the terms including “DNA-dependent DNA replication”, “mitotic cell cycle process”, “cell cycle”, “mitotic cell cycle” and so on ([Figure 3A](#)). In the cellular component, the DEGs were enriched in the terms including “chromosome”, “chromosomal region”, “replication fork protection complex”, “replication fork” and so on ([Figure 3B](#)). In the molecular function, the DEGs were mainly classified into terms, including “3'-5' DNA helicase activity”, “catalytic activity, acting on DNA”, “DNA-dependent ATPase activity”, “DNA helicase activity” and so on ([Figure 3C](#)). For the KEGG analysis, the DEGs were significantly enriched in the pathways including “cell cycle, mitotic”, “cell cycle”, “DNA strand elongation”, “Unwinding of DNA” and so on ([Figure 3D](#)).

PPI Network Construction and Identification of Hub Genes

Firstly, the PPI network of the overlapping DEGs was constructed using the STRING database. As shown in [Figure 4](#), the constructed PPI network contains 87 nodes and 309 edges with an average node degree of 7.1. Furthermore, the PPI network was constructed using the Cytoscape software ([Figure 5A](#)), and the sub-modules of the PPI network was further analysed using the MCODE tool. Based on the MCODE analysis, one sub-module with a score of 16.5 was identified. The sub-module network contains 21 genes with 21 nodes and 165 edges, and the constructed PPI network was shown in [Figure 5B](#). The genes identified in the sub-module network were defined as hub genes for further analysis.

Figure 2 Screening of the overlapping DEGs among GSE138080, GSE113942 and GSE63514 datasets. The volcano plots of DEGs in (A) GSE138080, (B) GSE113942 and (C) GSE63514; blue dots and pink dots represent the significantly down-regulated and up-regulated DEGs respectively. (D) The up-regulated and down-regulated overlapping DEGs were illustrated in the Venn diagram.

Expression Analysis of Hub Genes

The expression of the hub genes in the normal cervical tissues and cervical cancer tissues was analysed by the GEPIA. In the GEPIA datasets, 13 normal cervical tissues and 306 cervical cancer tissues were included in the analysis. As shown in Figure 5, all the 21 hub genes were significantly up-regulated in the cervical cancer tissues when compared to the normal cervical tissues (Figure 6).

Overall Survival Analysis of Hub Genes in Patients with Cervical Cancer

The correlation between hub genes and the overall survival of patients with cervical cancer was analysed by the GEPIA. In the analysed datasets, a total of 292 patients with cervical cancer were included in the analysis. Based on the median values of hub gene expression, the patients were classified into low expression and high expression groups. As shown in Figure 7, the low expressions of cell division

cycle 45 (*CDC45*), *GENS* complex subunit 2 (*GENS2*), minichromosome maintenance complex component 2 (*MCM2*) and proliferating cell nuclear antigen (*PCNA*) were significantly correlated with the shorter survival of patients with cervical cancer (Figure 7A–D); whereas the other hub genes were not associated with the overall survival of the patients with cervical cancer (Supplemental Figure S1). Further validation studies using Human Protein Atlas database and KM plotter showed that low expression of *CDC45*, *GENS2*, *MCM2* and *PCNA* predicted worse prognosis of patients with cervical cancer (Figures 8 and 9). Furthermore, the protein expression of *CDC45*, *GENS2*, *MCM2* and *PCNA* in the cervical cancer tissues and normal cervical tissues was evaluated by immunohistochemistry using the Human Protein Atlas database; as shown in Figure 9, the protein expression levels of *GENS2*, *MCM2* and *PCNA*, but not *CDC45* were significantly higher in the cervical cancer tissues than that in the normal cervical tissues (Figure 10).

Figure 3 Functional enrichment analysis of the overlapping DEGs. The GO enrichment analysis of DEGs in the categories of (A) biological process, (B) cellular component and (C) molecular functions. The top 10 enriched GO terms in each category were shown. (D) The KEGG pathway enrichment analysis of the overlapping DEGs. The top 10 enriched KEGG pathways were shown.

Effects of MCM2 Knockdown on the Cell Proliferation of HeLa and SiHa Cells

Among these hub genes, *MCM2* belongs to the MCM family, and emerging evidence implied that the MCM family members were key mediators in the cancer biology.^{18,19} Among the MCM members, the role of *MCM2* in cervical cancer development and progression remains unclear, thus, we performed validation studies on *MCM2*. The effects of *MCM2* knockdown on the cervical cancer cell proliferation were determined by CCK-8 and EdU incorporation assays, respectively. As shown in Figure 11A, the transfection of *MCM2* siRNA (si*MCM2*) significantly down-regulated the *MCM2* mRNA expression in both HeLa and SiHa cells. CCK-8 assay showed that *MCM2* knockdown suppressed the HeLa and SiHa cell proliferation (Figure 11B and C). The EdU incorporation assay consistently showed that *MCM2* siRNA transfection significantly reduced the EdU-positive HeLa and SiHa cells as compared to the siNC group (Figure 11D).

Discussion

Cervical cancer is one of the most common female malignancies, and great improvements have been made in the prevention and treatment of cervical cancer.¹ However, the molecular mechanisms underlying cervical cancer progression are not clear. With the advancement of the high throughput technologies, the novel biomarkers for cancer progression have been identified via analysing the microarray datasets. In the present study, we analysed 3 GEO datasets including GSE138080, GSE113942 and GSE63514; and a total of 89 overlapping DEGs (63 up-regulated and 26 down-regulated genes) were identified among the datasets. The functional enrichment analysis indicated that the overlapping DEGs were mainly associated with “DNA replication” and “cell cycle”. Furthermore, the PPI network analysis revealed a network with 87 nodes and 309 edges. Sub-module analysis using MCODE identified 21 hub genes from the PPI network. The expressions of the 21 hub genes were all

Figure 4 PPI network construction of the overlapping DEGs using STRING database.

Figure 5 PPI network construction and hub genes identification using Cytoscape. **(A)** The PPI network of the overlapping DEGs were constructed in Cytoscape software. **(B)** The sub-module of the PPI network was illustrated using the MCODE tool.

Figure 6 Expression analysis of hub genes in the cervical tissues. The expression levels of ANLN, CCNB2, CDC45, CDCA5, CENPF, CENPN, DTL, GINS2, KIF2C, KIF23, MCM2, MCM4, MCM5, MCM7, NEK2, NUSAP1, PCNA, PRC1, SPAG5, TPX2 and ZWINT in the normal cervical tissues and cervical cancer tissues were analysed using the GEPIA tool.

up-regulated in the cervical cancer tissues when compared to normal cervical tissues as analysed by the GEPIA tool. The survival analysis showed that the low expression of *CDC45*, *GINS2*, *MCM2* and *PCNA* was significantly correlated with the shorter survival of patients with cervical

cancer. Moreover, the protein expression levels of *GINS2*, *MCM2* and *PCNA*, but not *CDC45* were also significantly up-regulated in the cervical cancer tissues when compared to normal cervical tissues. Based on the above results, our analysis revealed four hub genes including *CDC45*,

Figure 7 Overall survival analysis of hub genes using the GEPIA tool. The association between the expression levels of *CDC45* (A), *GINS2* (B), *MCM2* (C) and *PCNA* (D) and overall survival of the patients with cervical cancer was analysed by using the GEPIA tool.

GINS2, *MCM2* and *PCNA* may be associated with the prognosis of patients with cervical cancer.

In our study, we found that *CDC45* was up-regulated in the cervical cancer tissues and predicted a better prognosis of patients with cervical cancer. In the KEGG pathway enrichment analysis, *CDC45* was classified into cell cycle pathway. *CDC45* has a critical role in the initiation and elongation steps of DNA replication to ensure that chromosomal DNA is replicated only once per cell cycle.²⁰ In the esophageal squamous cell carcinoma, *CDC45* can be suppressed ring finger protein 1 and Yin Yang 1-binding

protein, which exerted the tumor-suppressive effects on this malignancy.²¹ *CDC45* could promote papillary thyroid cancer progression via regulating cell cycle.²² Studies from Huang et al, indicated that *CDC45* functioned as an oncogenes in non-small cell lung cancer.²³ *KNK437* could destabilize *CDC45*, which lead to the suppression of colorectal cancer growth and metastasis.²⁴ In the bioinformatics analysis, *CDC45* was found to be up-regulated in colorectal cancer,²⁵ hepatocellular carcinoma,²⁶ and breast cancer tissues.²⁷ In colorectal cancer, low expression of *CDC45* predicts poor prognosis of patients with colorectal

Figure 8 Overall survival analysis of hub genes using the KM plotter (<https://kmplot.com/analysis/index.php?p=background>). The association between the expression levels of *CDC45* (A), *GINS2* (B), *MCM2* (C) and *PCNA* (D) and overall survival of the patients with cervical cancer was analysed by using the KM plotter.

cancer, which can be explained as *CDC45* being down-regulated in colorectal cancer tissues with advanced stage.²⁵ The bioinformatics studies showed that *CDC45* was up-regulated in the cervical cancer tissues and a high expression of *CDC45* was correlated with longer overall survival of patients with cervical cancer.^{28,29} Our findings were consistent with the previous studies, suggesting the robust bioinformatics analysis in this study. However, the expression of *CDC45* may be investigated in the cervical

cancer tissues with different clinical stages, which can further reveal the prognostic role of *CDC45* in the cervical cancer.

GINS2 belongs to the tetrameric complex family and functions as the replicative helicase, unwinding duplex DNA ahead of the moving replication fork. The role of *GINS2* has been deciphered in various types of cancers. A high *GINS2* transcript level predicts poor prognosis and correlates with high histological grade and endocrine

Figure 9 Overall survival analysis of hub genes using the Human Protein Atlas database (<https://www.proteinatlas.org/>). The association between the expression levels of *CDC45* (A), *GINS2* (B), *MCM2* (C) and *PCNA* (D) and overall survival of the patients with cervical cancer was analysed by using the Human Protein Atlas database.

therapy resistance through mammary cancer stem cells in breast cancer patients,³⁰ and *GINS2* regulates matrix metalloproteinase 9 expression and cancer stem cell property in human triple negative breast cancer.³¹ *GINS2* promotes cell proliferation and inhibits cell apoptosis in thyroid cancer by regulating Cbp/p300-interacting transactivator 2 and lysyl oxidase like 2.³² knockdown of *GINS2* inhibits cell proliferation and tumorigenesis in human gliomas;³³ *GINS2* promotes EMT in pancreatic cancer via specifically stimulating extracellular signal-regulated kinase 1/2/mitogen-activated protein kinase signaling.³⁴ In the cervical cancer, Chen et al, found that *GINS2* was up-regulated in the SiHa cells and cervical cancer tissues.³⁵ However, the prognostic role of *GINS2* in cervical cancer remains unknown. Our bioinformatics analysis revealed that low expression of *GINS2* was associated with poor prognosis of patients with cervical cancer; however, the detailed mechanisms of *GINS2* in cervical cancer progression still requires further examination.

PCNA plays a key role in the DNA replication of mammalian cells and their small DNA tumour viruses. In the cervical cancer studies, Up-regulation of *PCNA* is closely associated with high-risk human papillomavirus

and progression of cervical intraepithelial neoplasia (CIN), but does not predict disease outcome in cervical cancer.³⁶ Kim et al, demonstrated that *PCNA* immunostaining enhanced diagnostic accuracy for high-grade cervical squamous intraepithelial lesion.³⁷ Madhumati et al, found that *PCNA* labelling index was increased with increasing severity of CIN lesions.³⁸ In agreement with the above studies, our results consistently identified the up-regulation of *PCNA* in the cervical cancer tissues. Although the analysis of the public database from this study indicated that low expression of *PCNA* predicted poor prognosis of patients with cervical cancer, the prognostic role of *PCNA* is still unclear; and future clinical studies are warranted to validate the prognostic role of *PCNA* in cervical cancer.

MCM2 belongs to the MCM protein complex which consists of six highly conserved proteins (*MCM2-7*) and plays an important role in the initiation of DNA replication and DNA unwinding due to its replicative helicase activity. The prognostic role of *MCM2* has been demonstrated in various types of cancers including breast cancer,³⁹ colon cancer,⁴⁰ liver cancer²⁶ and so on. In the cervical cancer studies, Kuku et al, performed the immunostaining for

Figure 10 Protein expression levels of hub genes (*CDC45*, *GINS2*, *MCM2* and *PCNA*) in the normal cervical tissues and cervical cancer tissues were analysed using the Human Protein Atlas database (<https://www.proteinatlas.org/>).

Notes: ** $P < 0.01$.

MCM2 in cervical cancer tissues and suggested that *MCM2* does not appear to predict disease grade, stage, or outcome of patients with cervical cancer.⁴¹ Filho et al, showed that HPV-infected cells strongly express *MCM2*; nevertheless, their data suggests that *MCM2* is not a good biomarker when comparing the different clinical stages of cervical cancer.⁴² Studies also showed that *MCM2* was over expressed in cervical cancer irrespective of clinico-pathological parameters,⁴³ which was consistent with our findings regarding the *MCM2* protein expression in cervical cancer using the Human Protein Atlas database. A recent study suggested that a strong expression of *MCM2* protein in a high grade squamous intraepithelial lesion may aid as a concatenated screening tool in detecting pre-cancerous cervical lesions.⁴⁴ In our study, the bioinformatics result showed that up-regulated *MCM2* in the cervical cancer tissues may predict longer overall survival of patients with cervical cancer. The in vitro studies have shown that *MCM2* mRNA was enriched in HeLa cells to approximately four times the level in WI-38 cells.⁴⁵ In other types of cancers such as ovarian and lung cancer, *MCM2* was found to promote the proliferative potential of these cancer cells.^{46,47} In our in vitro functional studies, we consistently showed that *MCM2* knockdown suppressed the proliferation of HeLa and SiHa cells,

suggesting that *MCM2* may play an oncogenic role in the cervical cancer progression. However, the prognostic role of *MCM2* in cervical cancer is still controversial among studies, as a high expression of *MCM2* showed better prognosis for patients with cervical cancer as shown in our bioinformatics analysis. Indeed, studies have found a strong correlation between the *MCM2*-positive cells and the presence of HPV DNA detected by *in situ* hybridization. The database for the cervical patients may not be stratified according to the clinical characteristics of the patients, and future studies should stratify the patients based on clinical characteristics such as HPV-infection, tumor stage, etc to further confirm the prognostic role of *MCM2*.

The evidence regarding the prognostic role of *MCM2* was mainly based on the online bioinformatics tools in our study, and the exact prognostic role of *MCM2* still requires detailed examination using clinical data from a large cohort of patients with cervical cancer from multiple centres. The present study only analysed three GEO datasets, and future studies may screen more DEGs to further explore novel targets or confirm the role of *MCM2* in cervical cancer progression. Unfortunately, our experimental studies were limited to the in vitro assays, and further in vivo assays should be considered to examine

the role of *MCM2* in tumor growth. Finally, the regulatory mechanism of *MCM2* in cervical cancer is worthy of further investigation.

In conclusion, we screened a total of 89 overlapping genes from the GEO datasets, and further analysis identified four hub genes (*CDC45*, *GINS2*, *MCM2* and *PCNA*) that were likely associated with the prognosis of patients with cervical cancer. *MCM2* knockdown repressed the cervical cancer cell proliferation. The current findings may provide novel insights into understanding the pathophysiology of cervical cancer and develop therapeutic targets for patients with cervical cancer. Future validation studies are required to confirm the prognostic role and mechanistic actions of the hub genes in cervical cancer.

Cancer Management and Research

Publish your work in this journal

Cancer Management and Research is an international, peer-reviewed open access journal focusing on cancer research and the optimal use of preventative and integrated treatment interventions to achieve improved outcomes, enhanced survival and quality of life for the cancer patient.

Submit your manuscript here: <https://www.dovepress.com/cancer-management-and-research-journal>

Dovepress

The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
