Aim: Growth differentiation factor 15 (GDF15) is closely related to obesity. This study aimed to explore the influence of weight loss intervention on serum GDF15 levels and the relationship between GDF15 and metabolism.

Materials and Methods: Forty-four overweight and obese adults either adopted a low-carbohydrate diet or performed moderate-to-vigorous exercise for 3 weeks. Weekly follow-ups were conducted to measure body composition, glucose and lipid metabolism and serum GDF15 levels.

Results: After 3 weeks of intervention, body weight, fat mass and waist circumference in both groups decreased ($P < 0.05$). No significant change in GDF15 levels was observed in the two groups. Among all the subjects, 10 of them (22.7%, group of Down) showed a decrease in GDF15 and 34 (77.3%, group of Up) showed an increase in GDF15 after the intervention. We found that GDF15 increased significantly with the follow-up time in the UP group and waist circumference, fasting serum insulin (FINS), homeostasis model assessment of insulin resistance (HOMA-IR) and triglycerides (TG) decreased (P for trend < 0.05). However, no significant differences in all parameters were detected in Down group. In addition, GDF15 was elevated between 30 mins and 120 mins in a 75-g oral glucose tolerance test. Its trend was negatively correlated with plasma glucose and serum insulin.

Conclusion: Increased serum GDF15 was associated with improvement in metabolism by lifestyle intervention among young overweight and obese adults. The increase of GDF15 could be an indicator to evaluate metabolic improvements in overweight and obese people.

Introduction

Obesity has become one of the most important issues of global public health. Lifestyle adaptations including dietary adjustments and physical exercises are basic methods for weight loss,¹ which can reduce both subcutaneous and visceral fat and improve metabolism.^{2,3} It has been reported that the occurrence of obesity and obesity-associated diseases are closely related to many hormones and cytokines.^{4,5} For example, inflammatory factors like interleukin 6 and tumor necrosis factor α were found elevated in obese people, while anti-inflammatory cytokines like adiponectin decreased.⁶⁻⁸ Diets and regular exercise are able to affect the production of these cytokines.^{9,10}

Growth differentiation factor 15 (GDF15), also known as macrophage inhibitory cytokine-1, is a member of the transforming growth factor- β superfamily. It is expressed in various cells including adipocytes.^{11,12} Previous studies have confirmed its close relationship with obesity,¹² establishing its new role as a factor that regulates energy metabolism and homeostasis. In addition, GDF15 knockout mice were more prone to high fat diet-induced obesity with aberrant glucose tolerance, lowered locomotor activity and metabolic rate.¹³

At present, the influence of weight loss intervention on circulating levels of GDF15 in obese people was rarely investigated. To further explore the associations between GDF15 and obesity, the study enrolled overweight and obese adults and measured their serum GDF15 concentrations during a 3-week lifestyle intervention, assessing the changes of GDF15 levels and metabolism status.

Materials and Methods

Study Subjects

All subjects provided written informed consent before enrollment. The study was approved by the Ethics Committees of Shanghai Jiao Tong University Affiliated Sixth People's Hospital and complied with the Declaration of Helsinki. This trial was registered at www.chictr.org.cn with clinical trial registration number ChiCTR1800016786.

The study recruited overweight or obese subjects from the outpatient clinic at the Department of Endocrinology and Metabolism of Shanghai Jiao Tong University Affiliated Sixth People's Hospital from July 2018 to January 2019. The inclusion criteria were defined as follows: (i) aged from 18 to 40 years old; (ii) Body mass index (BMI) ≥ 24 kg/m² and waist circumference of males ≥ 90 cm or female ≥ 85 cm.¹⁴ Fifty-one subjects were prescreened by phone or message. None of the subjects had diabetes, severe liver, kidney or thyroid dysfunction, malignant tumor, infectious disease, pregnancy or lactation, history of medicine that might influence metabolism. None of the subjects had a history of cardiovascular disease. None of them had taken weight loss interventions within 1 month before the study. All the subjects were of Chinese Han nationality. Among them, two subjects were excluded due to not within the BMI range; two subjects were excluded due to a history of thyroid surgery and lack of time to participate, respectively; two subjects were excluded for other reasons. None of the subjects was diagnosed with diabetes after a 75-g oral glucose tolerance test (OGTT). The diagnosis of diabetes is according to the 2010 American diabetes association

criteria.¹⁵ Finally, 45 overweight or obese subjects aged from 20 to 34 years were enrolled.

Study Protocol

All subjects underwent an OGTT and completed standardized questionnaires in the first visit (Visit 1, Day 0). Eligible subjects were randomly divided into the low-carbohydrate diet group (LC) or the exercise group (EX) by randomized digital table. Subjects in each group received detailed instructions about intervention measures by an investigator before they started.

Subjects in the LC were not prescribed a specific diet with exact composition. Restricted carbohydrate intake < 50 g/day for 3 weeks was required and there was no restriction of calories, proportion of fat and protein, water or black coffee intake. Fruits, vegetables, processed foods or drinks with high sugar content or high-glycemic index were also restricted. No additional exercise was needed. Subjects in the EX were required to maintain their usual diet and take moderate-to-vigorous exercise ≥ 30 mins/day for 3 weeks. Heart rate was required to reach 60% to 70% of their maximum predicted heart rate, which was calculated as 220 (210 for females) minus the subject's age per minute. No restriction of exercise types, but jogging, trotting, skipping and cycling were recommended. Interventions were conducted by participants themselves in free living.

All subjects were required to record their daily diet or exercise conditions by taking photos and filling in record forms assigned by investigators and upload photos to investigators every day. The follow-ups were conducted at the end of week 1 (Visit 2, day 8), week 2 (Visit 3, day 15) and week 3 (Visit 4, day 22).

Anthropometric and Biochemical Measurements

Anthropometric parameters and fasting venous blood samples were collected in each clinical follow-up (except an OGTT in Visit 1). Body composition was assessed by the Tanita TBF-418 body composition analyzer (Tanita Cooperation, Tokyo, Japan). Height was measured by a metric tape at baseline. Waist circumference was measured over the midpoint between the inferior margin of the last rib and the iliac crest by a flexible non-elastic metric tape. BMI = weight (kg)/squared height (m²).

Venous blood samples were collected after an overnight fast (≥ 10 hours) and were used to measure fasting plasma glucose (PG_{0min} or FPG), fasting serum insulin

(INS_{0min} or FINS), fasting serum GDF15 (GDF15_{0min}), glycated haemoglobin A1c (HbA_{1c}), total cholesterol (TC), triglycerides (TG), high-density lipoprotein cholesterol (HDL-c) and low-density lipoprotein cholesterol (LDL-c). All subjects underwent a 75-g OGTT to measure 30-min plasma glucose (PG_{30min}), 30-min serum insulin (INS_{30min}), 30-min serum GDF15 (GDF15_{30min}), 120-min plasma glucose (PG_{120min}), 120-min serum insulin (INS_{120min}) and 120-min serum GDF15 (GDF15_{120min}).

Plasma glucose and serum lipids were measured by a biochemical analyzer (Hitachi 7600–120, Tokyo, Japan). HbA_{1c} was measured by using high-performance liquid chromatography with a VARIANT II Hemoglobin A1c analyzer (Bio-Rad Laboratories, Hercules, CA). Serum insulin was measured by an electrochemiluminescence immunoassay on a Cobas e601 analyzer (Roche Diagnostics GmbH, Mannheim, Germany). Serum GDF15 levels were determined by quantitative sandwich enzyme-linked immunosorbent assay (R&D Systems, Minneapolis, USA) with intra- and inter-assay coefficients of variation (CV) 0.46%–4.08% and 5.77%–9.24%, respectively. The CVs were determined at the concentrations of 100 pg/mL, 200 pg/mL, 400 pg/mL, 800 pg/mL and 1200 pg/mL (supplementary Table 1). The limit of quantitation (LoQ) of GDF15 ranged from 0.0 to 4.4 pg/mL and the mean LoQ was 2.0 pg/mL. The assay measuring range was 0–1500 pg/mL and the expected range in health was 337–1060 pg/mL in this assay. The homeostasis model assessment-insulin resistance (HOMA-IR) = FPG (mmol/L) × FINS (mU/L)/22.5.

Statistical Analysis

Statistical analyses were carried out using the SPSS 20.0 software (SPSS Inc., Chicago, IL, USA). The Kolmogorov–Smirnov test was performed to determine the normality of the data distribution. Data with a normal distribution were expressed as the mean ± standard error, and data with skewed distribution were expressed as median with interquartile range. Categorical variables were expressed as numbers with percentages. Comparisons between the two groups were carried out using the Student's *t* test (normal distribution) or the Mann–Whitney *U*-test (skewed distribution). One-way repeated-measure ANOVA (Bonferroni correction included) was used to analyze differences from time 0 min to time 30 min and time 120 min in OGTT and differences from baseline to the 8-day, 15-day and 22-day follow-ups in the same group. Pearson correlation analysis was used to determine the relationship between the change of GDF15 and other metabolic parameters. Multivariate stepwise regression analysis was used to evaluate influential factors on change of GDF15. Cohen's

d was used to calculate the effect size ($d = \frac{X_1 - X_2}{S_{pooled}}$, $S_{pooled} = \sqrt{\frac{(n_1 - 1)S_1^2 + (n_2 - 1)S_2^2}{n_1 + n_2 - 2}}$). A multivariate generalized estimating equation model adjusted for gender, age, follow-up visits, obesity status, family history of obesity, diabetes mellitus and other confounding factors was used to evaluate influential factors on GDF15. A *P* value (two sides) <0.05 was considered statistically significant.

Results

Basic Characteristics of the Study Subjects

Overall, 22 subjects in the LC and 22 subjects in the EX (Total 45 subjects, 1 subject quit due to lack of time) finished the study and none of them had a smoking history. All the baseline

Table 1 Baseline Characteristics of Study Participants

Variable	LC	EX	P
Male/female	13/9	16/6	0.526
Age (years)	25.36 ± 0.75	24.27 ± 0.43	0.213

INS _{120min} (μU/mL)	61.99 ± 9.32	86.76 ± 14.23	0.153

Notes: Data are presented as mean ± SEM or median (interquartile range). Analyzed by Independent-samples *t* test and chi-square test.

Abbreviations: LC, low-carbohydrate diet group; EX, exercise group; BMI, body mass index; W, waist circumference; TC, total cholesterol; TG, triglycerides; HDL-c, high-density lipoprotein cholesterol; LDL-c, low-density lipoprotein cholesterol; CRP, c-reactive protein; HbA_{1c}, glycated hemoglobin A1c; PG_{0min}, fasting plasma glucose; PG_{30min}, 30-min plasma glucose; PG_{120min}, 120-min plasma glucose; INS_{0min}, fasting serum insulin; INS_{30min}, 30-min serum insulin; INS_{120min}, 120-min serum insulin.

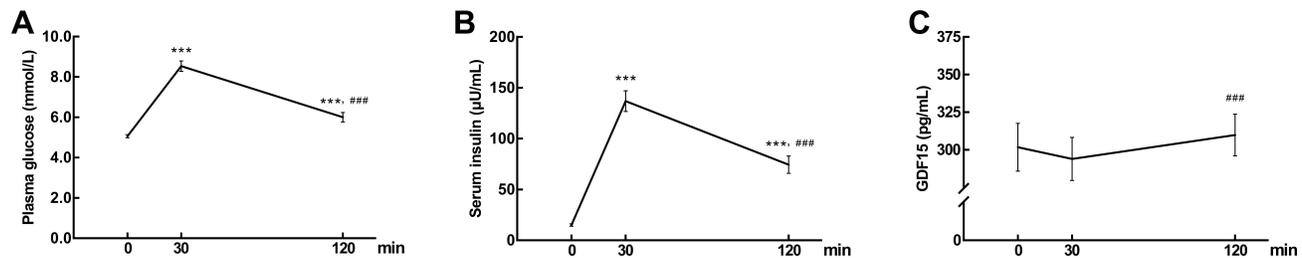

Figure 1 (A) Plasma glucose (B) serum insulin and (C) GDF15 concentrations over 120 min in response to a 75 g oral glucose tolerance test (OGTT). Data are expressed as mean \pm SEM. *** $P < 0.001$ compared to time 0 min and #### $P < 0.001$ compared to time 30 min.

characteristics had no significant difference between the two groups (Table 1).

Serum GDF15 Levels in OGTT

During OGTT ($n = 44$), plasma glucose and serum insulin sharply increased first and then decreased (Figure 1A and B). GDF15_{30min} (294.02 ± 14.33 pg/mL) showed a slight decrease, not significantly different from GDF15_{0min} (301.80 ± 15.93 pg/mL). After 120 mins' high glucose loading, GDF15_{120min} (309.84 ± 13.90 pg/mL) rebounded to baseline level, significantly higher than GDF15_{30min} ($P < 0.05$, Figure 1C). The differences between the GDF15_{120min} and GDF15_{30min}, PG_{120min} and PG_{30min}, INS_{120min} and INS_{30min} were represented as Δ GDF15_{120min-30min}, Δ PG_{120min-30min}

and Δ INS_{120min-30min}, respectively. Pearson correlation analysis showed that Δ GDF15_{120min-30min} was negatively correlated with Δ PG_{120min-30min} ($r = -0.358$, $P < 0.05$) and Δ INS_{120min-30min} ($r = -0.496$, $P < 0.05$).

Serum GDF15 Levels During Interventions

After 3-week interventions, body weight, fat mass and waist circumference in both groups decreased compared to baseline ($P < 0.05$, Figure 2A–C). However, no significant change in serum GDF15 levels was observed in the two groups (Figure 2D). The baseline and endpoint levels of GDF15 in LC and EX groups were in [supplementary Table 2](#). GDF15 levels of each subjects in week 1, week 2

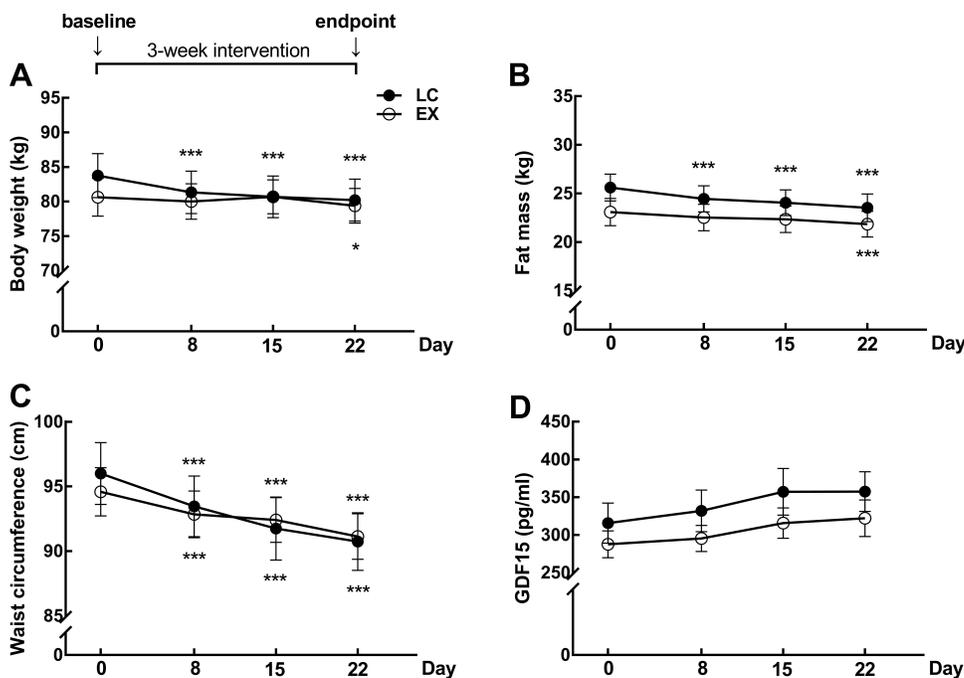

Figure 2 (A) Body weight (B) Fat mass and (C) Waist circumference and (D) serum fasting GDF15 concentrations during the follow-ups in low-carbohydrate group ($n = 22$) and exercise group ($n = 22$). Data are expressed as mean \pm SEM. * $P < 0.05$, *** $P < 0.001$ compared to baseline (Day 0).

Table 2 Multivariate Linear Regression Analysis of Δ GDF15

	β	t	P
Intervention means	0.138	0.901	0.373
Δ weight	0.117	0.667	0.509
Δ waist circumference	-14.257	-2.947	0.005

Note: The variables included were the intervention means, gender, age, Δ weight, Δ BMI, Δ fat mass, Δ waist circumference, Δ FPG, Δ FINS, Δ HOMA-IR, Δ TC, Δ TG, Δ HDL and Δ LDL.

and week 3 were in [supplementary Table 3](#). All the parameters between the two groups had no significant difference during the study.

Relationship of GDF15 with Studied Parameters

To evaluate the association between Δ GDF15 and the intervention means, we performed a stepwise regression analysis with Δ GDF15 as the dependent variable ([Table 2](#)). We found that after adjusting for confounding factors including gender, age, Δ weight, Δ BMI, Δ fat mass, Δ waist circumference, Δ FPG, Δ FINS, Δ HOMA-IR, Δ TC, Δ TG, Δ HDL and Δ LDL, intervention means was not an influential factor for GDF15 ($P = 0.373$).

Therefore, data of 44 subjects were further analyzed together. Mean serum GDF15 levels of 44 subjects increased compared to baseline (V4: 339.79 ± 17.86 pg/mL vs V1: 301.80 ± 15.93 pg/mL, $P < 0.05$). Pearson correlation analysis was used to analyze the relationship between Δ GDF15 and Δ weight, Δ BMI, Δ waist circumference, Δ FBG, Δ FIN, Δ lipid. The results showed that Δ GDF15 was negatively correlated with Δ waist circumference ($r = -0.414$, $P < 0.05$) and Δ FPG ($r = -0.318$, $P < 0.05$), which indicated that increased GDF15 might be associated with improvement in metabolism.

Among all the participants, 10 subjects' GDF15 (22.7%) decreased and 34 subjects' GDF15 (77.3%) increased

compared to their baseline levels ([Figure 3A and B](#)). Subjects were then divided into another two groups according to their changes of GDF15 (Down: $n = 10$ and Up: $n = 34$, [Table 3](#)). Changes of parameters between baseline and endpoint in UP and DOWN groups were presented in [supplementary Table 4](#). A multivariate generalized estimating equation model was used to analyze changes in the GDF15 and other metabolic parameters with adjustments for confounding factors including gender, age, obesity status, family history of obesity and diabetes mellitus. The results showed that in the Up group, GDF15 tended to increase significantly with the follow-up time (P for trend < 0.05) along with the decreased trend of waist circumference, FINS, HOMA-IR and TG (P for trend < 0.05). However, in the Down group, all comparisons were nonsignificant.

Discussion

It has been reported that GDF15 is implicated in multiple biological processes, including inflammatory response, oxidative stress and energy homeostasis,¹¹ susceptible to metabolic alternations. Previous studies also found that diets and exercise could affect GDF15 levels,¹⁶⁻¹⁸ but no comparative study has been conducted before and the influence of low-carbohydrate diets (LCD) on GDF15 is not clear yet. Patal et al¹⁷ found GDF15 levels of obese people were elevated after taking low-calorie meals and reduced during overeating. Furthermore, regular aerobic exercises (12 weeks) increased circulating GDF15 levels in obese people and the elevation in plasma GDF15 was associated with the loss of fat mass.¹⁸ Our study first investigated the effect of LCD on serum GDF15 and compared it with the effect of exercise. We found that lifestyle intervention could increase serum GDF15 and the changes of GDF15 had no connection with the means of intervention.

In accordance with the results of the present study, GDF15 was elevated as well in other conditions of weight loss such as anorexia nervosa and bariatric surgery.¹⁹⁻²¹ The mechanisms underlying the role of GDF15 in metabolic regulation are

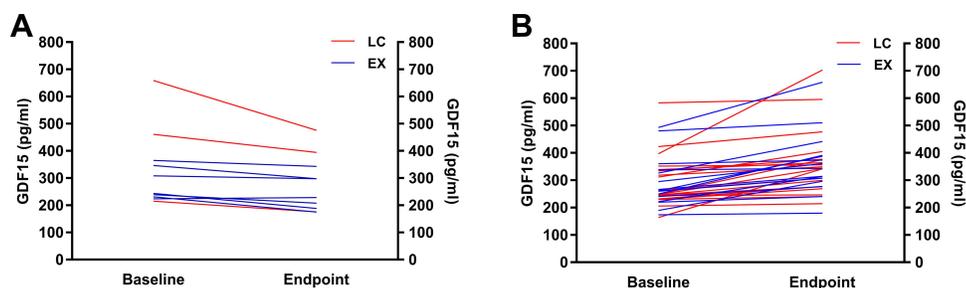

Figure 3 (A) The downtrend ($n = 10$) and (B) uptrend ($n = 34$) of fasting serum GDF15 concentrations before and after interventions.

Abbreviations: LC, low-carbohydrate diet group; FH, family history; DM, diabetes mellitus; GDF15, fasting serum growth differentiation factor 15; BMI, body mass index; FM, fat mass; VV, waist circumference; FPG, fasting plasma glucose; FINS, fasting serum insulin; HOMA-IR, homeostasis model assessment of insulin resistance; HbA_{1c}, glycosylated hemoglobin A1c; TC, total cholesterol; TG, triglycerides; HDL-c, high-density lipoprotein cholesterol; LDL-c, low-density lipoprotein cholesterol.

complicated. Glial cell line-derived neurotrophic factor family receptor α -like (GFRAL) was identified as the neuronal brain-stem receptor responsible for mediating the anorectic actions of GDF15.^{22,23} Besides, GDF15 prevents obesity by increasing the expression of key thermogenic and lipolytic genes to promote thermogenesis, lipolysis and oxidative metabolism.²⁴ Furthermore, GDF15 can mediate its effects by central mechanisms like hypothalamic transforming growth factor-beta receptor II, neuropeptide Y and so on.²¹ The latest study has revealed that the effects of metformin on body weight and energy balance are also mediated by GDF15.²⁵

We found that lifestyle intervention could increase serum GDF15 in overweight and obese people. A previous study also showed that a two-week very low-calorie diet (VLCD) significantly increased serum GDF15 levels, reduced body weight and improved metabolism in obese people.¹⁶ However, they also found that GDF15 in diabetic patients did not change after VLCD in spite of a similar reduction of body weight and metabolic parameters. Therefore, they concluded that increased GDF15 levels in obese patients and diabetic patients do not induce weight loss. In combination with their conclusions and our results, we did not consider the increase of GDF15 as the cause of weight loss or improvement in metabolism. The possible association between them suggested GDF15 as a biomarker to assess the validity of obesity intervention.

The study showed GDF15 slightly descended first and then significantly increased during high glucose load which was contrary to the variation trend of blood glucose and insulin. One study had consistent findings that GDF15 decreased first and increased back to baseline levels at 120 min in OGTT.²⁶ Although Patal¹⁷ et al suggested that GDF15 levels were unchanged following glucose ingestion, their data showed circulating GDF15 levels briefly fell at 60 min time point after the mixed meal. This variation trend was also similar to our results. So far studies about the response of GDF15 to glucose load are rare and the exact mechanism remains to be further investigated. Our data suggest whether the acute change of GDF15 under high glucose load or the chronic change after lifestyle intervention, the changes of GDF15 are opposite to that of glucose and insulin. Moreover, the increase of GDF15 may be associated with improved metabolism and the relationship was independent of weight loss since body weight remained stable during OGTT.

This study has some limitations. First, the study period was relatively short so that the evaluation of metabolic levels and cytokines might be inadequate. Additionally, it was a single-center open study with a small sample size. Therefore, further

long-term large-scale randomized clinical trials are needed to explore the relation among GDF15, obesity and metabolism.

Conclusion

In summary, this study found increased serum GDF15 was associated with improvement in metabolism by lifestyle intervention among young overweight and obese adults. The increase of GDF15 could be an indicator to evaluate metabolic improvements in overweight and obese people.

Author Contributions

All the authors have made a significant contribution to the study in the conception, study design, execution, acquisition of data, analysis and interpretation. All the authors took part in drafting, revising or critically reviewing the article. And all the authors gave final approval of the version to be published and agree to be accountable for all aspects of the work.

Funding

The authors are grateful to all the participants in the study. This study was supported by the Shanghai Municipal Education Commission—Gaofeng Clinical Medicine

Grant Support (20172025) and the National Natural Science Foundation of China (82070885).

Disclosure

The authors declared no conflict of interest.

Diabetes, Metabolic Syndrome and Obesity: Targets and Therapy

Dovepress

Publish your work in this journal

Diabetes, Metabolic Syndrome and Obesity: Targets and Therapy is an international, peer-reviewed open-access journal committed to the rapid publication of the latest laboratory and clinical findings in the fields of diabetes, metabolic syndrome and obesity research. Original research, review, case reports, hypothesis formation, expert opinion

and commentaries are all considered for publication. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
