Abstract: Light therapy for older persons with dementia is often administered with light boxes, even though indoor ambient light may more comfortably support the diverse lighting needs of this population. Our objective is to investigate the influence of indoor daylight and lighting on the health of older adults with dementia living in long-term care facilities. A systematic literature search was performed within PubMed, CINAHL, PsycINFO, Web of Science and Scopus databases. The included articles (n=37) were published from 1991 to 2020. These articles researched the influence of existing and changed indoor light conditions on health and resulted in seven categories of health outcomes. Although no conclusive evidence was found to support the ability of indoor light to decrease challenging behaviors or improve circadian rhythms, findings of two studies indicate that exposure to (very) cool light of moderate intensity diminished agitation. Promising effects of indoor light were to reduce depressive symptoms and facilitate spatial orientation. Furthermore, there were indications that indoor light improved one's quality of life. Despite interventions with dynamic lighting having yielded little evidence of its efficacy, its potential has been insufficiently researched among this study population. This review provides a clear and comprehensive description of the impact of diverse indoor light conditions on the health of older adults with dementia living in long-term care facilities. Variation was seen in terms of research methods, (the description of) light conditions, and participants' characteristics (types and severity of dementia), thus confounding the reliability of the findings. The authors recommend further research to corroborate the beneficial effects of indoor light on depression and to clarify its role in supporting everyday activities of this population. An implication for practice in long-term care facilities is raising the awareness of the increased lighting needs of aged residents.

Keywords: lighting, Alzheimer's disease, assisted living, nursing homes, indoor daylight, light therapy

Introduction

Although Western governmental policies encourage aging-in-place, the number of persons with dementia living in long-term care facilities is still growing. According to the World Health Organization,¹ dementia is one of the major causes of disability and dependency among older people. Therefore, we would expect long-term care facilities to offer an optimal physical environment that would support older persons

with dementia and accommodate for their losses. However, the physical environment, including indoor light, is often an undervalued and even ignored resource in dementia care.²⁻⁴ Indoor daylight and lighting are essential elements of an optimal environment to compensate for age- and dementia-related sensory changes.^{5,6}

Due to the aging of the eyes, older people have an increasing demand for higher light levels that support good vision and help synchronize their biological clock.^{7,8} Sufficient light for visual needs helps older people to (independently) execute activities of daily living, hobbies and social activities. The light aids them in not only moving safely but to also feeling safe.⁹ In addition, high-intensity light during daytime is needed, because it is the strongest cue for synchronizing the biological clock with the 24-hour rhythm of the earth.^{10,11} In turn, the biological clock plays an important role in the timing and coordination of physiological and psychological processes with a circadian (24 h) rhythm, including hormone levels, body temperature, alertness, urine production and composition, sleep-wake rhythm, mood and performance.¹²⁻¹⁵ Despite the lighting needs of older persons, the literature shows that the light conditions in long-term care facilities are poor, both for visual needs as well as for entraining the biological clock.¹⁶⁻¹⁹

Ensuring good quantity and quality of indoor light is even more important for older persons with dementia. For instance, in winter, this group is more sensitive to circadian disruption than healthy older adults.²⁰ Increasing dementia severity can lead to increasing sleep-wake rhythm disturbances, which in extreme cases may lead to complete day and night sleep pattern reversals.^{21,22} In addition, specific dementia-related changes in the brain result in difficulties in finding objects, reading, depth perception, perceiving structure from motion, color recognition and impairment in spatial contrast sensitivity.²³ It is to be expected that sufficient light that supports good vision can help compensate for these changes as well as improve orientation of older adults with dementia.

Light therapy, which focuses on changes in the circadian pacemaker in the brain, is an emerging therapy within the domain of dementia care.²⁴ While light therapy can be administered in a number of ways, the use of a light box standing on a table in front of the person with dementia is to date the most frequently applied and researched method.²⁵ However, using light boxes for persons with dementia presents some disadvantages. To

remain sitting in front of a light box for a minimum of 30 minutes and up to 2 hours per day may be difficult for persons with dementia,²⁶ even if the intervention takes place while performing other activities, such as having meals or watching television. The exposure may require supervision,^{26,27} which in turn puts a strain on the participants as well as on the supervisor. In contrast, indoor environmental light may be a preferable source because it allows for free movement.²⁸ In recent years, the use of dynamic lighting for this population has become increasingly popular, not in the least due to the often unproven claims of their suppliers. Dynamic lighting changes during the day in illuminance or spectral composition, or both, in such a way that the variation in light can be perceived by people.²⁹ Long-term care facilities have purchased dynamic lighting with the intention of improving the well-being and day-night rhythm of persons with dementia.³⁰

The foregoing paragraphs highlight the importance of indoor daylight and lighting and raises questions about the influence thereof. To date, there is no systematic review published that exclusively documents the influence of indoor environmental light conditions (daylight and lighting) on the health of older persons with dementia living in a long-term care facility. A Cochrane review on the effects of light therapy on persons with dementia included only one study with indoor environmental light.³¹ Their conclusions were based on studies where the light sources (light boxes, light visors, light fixtures) differed to such an extent that the results might not be comparable. Other reviews did not fully combine all three distinctive elements that this research is interested in: older adults with dementia, indoor environmental light and long-term care facilities. These reviews, for instance, were concerned with light therapy and dementia,³² daylight and health in general³³ or a therapeutic lighting design and older adults.³⁴ Therefore, the research question for this systematic literature review is the following: What does scientific literature tell us about the influence of indoor environmental light conditions (daylight and lighting) on the health of older adults with dementia living in a long-term care facility? Health is thereby defined as the ability to adapt and self-manage in the face of social, physical and emotional challenges.³⁵ Compared to the WHO-definition of health,³⁶ this definition of Huber et al better reflects the everyday reality of people with chronic diseases, including people with dementia.

Methods

Search Strategy

To identify relevant empirical studies, we conducted a systematic literature search in five scientific databases. We focused on databases related to health, medicine, nursing, behavioral and social sciences, as well as the built environment. Therefore, the databases PubMed, CINAHL, PsycINFO, Web of Science and Scopus were selected. Published studies were next identified using a search strategy based on the three facets of the research question: persons with dementia, light and long-term care facilities ([Supplementary Table](#)). The search string encompassed specific indexing terms and subject headings from the different databases as well as keywords, synonyms and some additional words that best represented the facet. The search included articles published up to May 2020 and resulted in 810 unique articles.

Article Selection

[Figure 1](#) shows the selection process of the articles. In the first selection phase, all duplicates were removed, and the remaining titles (n=810) were screened for inclusion by the first author (IG). When all selection criteria ([Table 1](#)) were met or in any cases of doubt, articles proceeded for further screening. In this second phase, two reviewers (IG and MV) independently assessed the abstracts of the remaining articles (n=354) and discussed the eligibility until they reached consensus. If consensus was not reached, the full research team was consulted. In the third phase, an identical procedure was followed for assessing the remaining full-text articles (n=99). Finally, the first author (IG) screened all references of the 35 included articles for any additional potentially relevant articles (snowball method). Eligibility of these articles was again checked by two reviewers independently (IG and LVB) and yielded two additional articles, which resulted in a total of 37 articles in this review.

Data Processing

Data from the 37 included articles were extracted independently by the first author and one of the other reviewers, and subsequently discussed in the same pairs (IG and LVB/MV/JVH). All reviewers used the same data extraction form consisting of the following categories:

1. Study, sample and setting characteristics,
2. Specifics on the light condition, lighting systems, light measurements and light-measuring equipment (based on recommendations by Aarts, Aries, Diakoumis, van Hoof),³⁸
3. Environmental properties (eg, location, date, weather conditions, daylight openings),
4. Health outcomes and assessment tools used,
5. Specifics on data collection methods and (statistical) analyses,
6. Appraisal of the methodological quality.

Because we included empirical studies regardless of their research design, we used the Mixed Methods Appraisal Tool (MMAT) for appraising a study's methodological quality.³⁹ The MMAT was comprised of two general screening questions and five specific methodological criteria for each type of research design. The maximum score of each type of design was five.

Results

Characteristics of Included Articles

The majority of the studies were conducted in North America (51.4%), followed by Europe (32.4%), Asia (10.8%), Australasia (2.7%) and in both Asia and Australasia (2.7%). For more detailed information about the characteristics and the results of the included articles see [. The articles were published from 1991 to 2020 and written in English. Most studies took place in \(dementia-specific care units of\) nursing homes, assisted living facilities or both. The research designs included the following categories: 12 quantitative descriptive studies, 19 quantitative non-randomized studies, 2 quantitative randomized controlled trials, 3 qualitative studies and 1 mixed methods study. Although the methodological quality of the studies varied, most studies reached MMAT quality scores of three or more out of five. Less attention was given to the results of two studies that received lower MMAT scores.^{30,40} The light conditions were often insufficiently described; eg, a number of studies lacked relevant data, such as characteristics of the light sources, or used subjective light measurements.](#)

Almost 60% (n=21) of the studies investigated the influence of existing indoor light conditions on health. In 16 studies (43.2%), the indoor light conditions were purposely changed before or during the study. These light interventions during the day consisted of an increase in the light intensity, color temperature or

both. This was done either by adding luminaires or replacing light bulbs, adding static or dynamic lighting systems, increasing the use of incident daylight through newly built skylights or by taking residents to a daylit room near the windows for socialization. Two

interventions took place around night-time, namely reduction of the frequency of light changes during incontinence care and a naturalistic simulation of dawn–dusk signals in the bedrooms of persons with dementia. Most of the light interventions took place in communal living

Table 1 Inclusion and Exclusion Criteria

Inclusion Criteria	Exclusion Criteria
Research investigating the influence of indoor daylight and/or lighting on health	Research on interventions with (supplementary) light boxes, light visors, light cues or light tables
Research in which participants are 60 years and older and have dementia	Research on immune suppression by light
Research in which participants live in a long-term care facility	Research aimed at extra visual effects of light on health (eg, through the skin instead of the eye) and/or on effects of non-visible light
Empirical research with a qualitative, quantitative or mixed methods design	Research conducted exclusively in (geriatric) hospitals, long-term care facilities for persons with psychiatric problems or for persons with intellectual disabilities who also have dementia
Original and peer-reviewed articles written in English, French, German or Dutch	

rooms, dining rooms, or both (n=12) and the rest occurred in bedrooms (n=3) or a small light therapy living room (n=1).

Influence of Light on Health

By examining and reporting the influence of light on health, two specific characteristics of light were classified: light level and color temperature. Light can differ in intensity, the light level, and its spectrum can, for example, be experienced as warm white or yellowish, cool white or even bluish, often referred to as the color temperature. The correct technical term is correlated color temperature (CCT) and depends on the type of light source. In this review, these two characteristics are used separately or in different combinations to indicate the light level and (correlated) color temperature of light (Table 3).

By categorizing all health outcomes in the literature into thematic groups, we identified seven categories of health outcomes (number of articles; percentage). We will discuss the outcomes in the following order:

1. Behavior, such as agitation, (neuro)psychiatric symptoms and apathy (n=22; 59.5%)

2. Daily functioning, such as activities of daily living, falls and food intake (n=9; 24.3%)
3. Mental functions, such as orientation, cognition and disturbances of consciousness (n=7; 18.9%)
4. Mood and emotions, such as depression and subjective emotions (n=8; 21.6%)
5. Quality of life (n=4; 10.8%)
6. (24h) Rest–activity rhythms or certain aspects thereof, such as daytime activity, rest–activity cycles, nocturnal restlessness and sleep (n=18; 48.6%)
7. Bodily functions: adverse effects of light, use of medication and visual performance (n=3; 8.1%).

Behavior

Behavior was the most investigated health outcome (n=22) in the literature, and most articles reported on sets of challenging behaviors (n=18; 81.8%), like agitation. The Cohen–Mansfield Agitation Inventory (CMAI), which consists of 29 distinctive behaviors, was often used in the research.⁴¹ Almost 30% (n=6) of the articles (also) researched one or more separate challenging behaviors, such as pacing or apathy. Only two studies also involved positive behaviors. In this review two types of influences of light on behavior were distinguished. First, articles were identified that investigated a direct influence of the quantity, quality or color of light on behavior, which we will discuss first (n=21). Second, a more indirect influence of light on behavior was found, namely temporal aspects of light, like day length or time of day (n=7).

Direct Influence of Light on Behavior

Six methodologically sound light intervention studies investigated the influence of cooler light (neutral to very cool) during the day on sets of challenging behaviors (MMAT score $\geq 3/5$). The majority of these light interventions (n=4; 66.7%) did not yield any significant influences on sets of challenging behaviors in the intervention group compared to a control condition.^{27,42–44} These ineffective interventions concerned light with a (very) high light intensity (Table 3) which was produced by lighting installations or was a result of incident daylight through a window. In two other studies, the lighting interventions resulted in a daytime light exposure of moderate intensity of (very) cool light.^{45,46} In these before–after studies (n=14;⁴⁵ n=12⁴⁶), agitation decreased significantly compared to the baseline condition. One of these studies found that the decrease in agitation was attributable to

Table 2 Characteristics of the Studies

Author (Year)	Methods, MMAT Type (Quality Score)	Participants	Setting (Country)	Light Conditions (Light Assessment)	Duration Light Intervention (Study Duration)	Health Categories and Health Outcomes	Health Assessment	Results
Aarts et al (2015) ³⁰	Survey; QDS (2/5)	n=17 care professionals	4 Psychogeriatric care facilities (The Netherlands)	Change in light conditions: 4 conditions 3 facilities: DLS and 1 facility: SLS. Average: activating: vertical 370 lx; 4130 K. rest light condition: vertical 217 lx; 3259 K (Light meter)	≈ 9–17 am (Not reported)	Be: behavior OH: use of sleep medication OH: visual performance DF: number of falls ReAc: activity nighttime, sleep, activity daytime	All: specifically designed questionnaires: effects on clients	No significant influences on all health outcomes.
Algase et al (2010) ⁵³	Descriptive, cross-sectional, correlational design; QDS (4/5)	n=122 individuals with dementia diagnosis and wandering behavior; M MMSE = 7.4 (n=114; SD=7.2) F 77%; M age 83.7 (SD = 6.48) y	22 Nursing homes + 6 assisted living facilities with dementia specific units (USA)	Existing light conditions: M ambient light level = 151.46 lx (SD = 298.70) (Light meter)	NA (2 nonconsecutive days)	Be: wandering behavior	Be: videotapes of 10–12 20-minute observations: rate and duration	-Light was significantly positively associated with wandering. -Ambient light level significantly predicted wandering.
Barrick et al (2010) ²⁷	Cluster-unit crossover design; QNRS (3/5)	n=20 older persons with moderate-very severe dementia (Oregon); F 95%; age 65–79 y (n=4) and ≥80 y (n=16)	1 Dementia-specific residential care facility (USA)	Change in light conditions: 4 conditions SLS in activity and dining areas. Bright (very high-intensity) light M 2638 lx: am (7–11), pm (4–8), all day (7 am–8 pm) and 'standard' light M 591 lx. Mean exposure was 2.64, 2.87, and 8.40 h daily during am, pm, and all day, resp. (Not reported)	8 Intervention periods of 3 weeks for all light conditions	Be: agitation	Be: hourly direct researchers' observation (6 am–8 pm; total 48h) Be: CMAI: reported observations care professionals	-CMAI was significantly higher in all day bright light than in am bright light. -No significant differences in CMAI for am, pm and all day bright light vs standard light. -Observed agitation: participants with moderate dementia were significantly more agitated under all three bright light conditions. than in standard conditions. -No significant differences between CMAI and day length (h) nor with the rate of change in day length over the 3-week intervention period (min/day).

Bicket et al (2010) ⁴⁸	Analytical cross-sectional study; QNRS (3/5)	n=194 residents with dementia; F 77.8%; M age 86.1 (± 8.1) y	21 Assisted Living Facilities (USA)	Existing light conditions: No specific information reported about the light conditions in the ALFs Light intensity: light glare and light evenness (TESS-NI/RC)	NA (3 weeks) TESS 1.5–5.5 years after baseline assessment	Be: neuropsychiatric symptoms OH: risk of falls QoL: quality of life	Be: NPI BF: falls in the last month as recalled by the resident and chart review QoL: ADRQL	-No significant relationship of light intensity, - glare and - evenness with NPI total score and with ADRQL. -Light glare was significantly negatively correlated with fall risk (n=187).
Blwise et al (1993) ⁶⁰	Behavioral observation study; QDS (4/5)	n=9 older adults with moderate-severe dementia; F 77.8%; age 82–92 y	Skilled Nursing Facility (USA)	Existing light conditions Averaged highest recorded illumination exposure for subjects: Autumn: 647 lx (SD = 372), Winter: 277 lx (SD = 164) (Light meter)	NA (From 1 pm to 1 am Autumn: 9 days in 3 weeks; Winter: 6 days in 3 weeks)	Be: agitation ReAc:sleep	Be: ABRs; ReAc: observations of being awake or asleep	-Agitation: autumn/winter: no significant effect for time of day. -Agitation: autumn: no significant effect for day of the week. Not measured in winter. -Agitation/sleep: No seasonal differences in the proportion of observations spent asleep/ agitated before or after sunset. -Sleep: autumn: no significant effect for time of day. -Sleep: winter: significantly less sleep during the sunset period.
Bromundt et al (2019) ⁴⁷	A balanced crossover, within-subject study; QNRS (4/5)	n=20 participants with (suspected) dementia: n=10 AD, n=5 VD, n=3 MD, n=1 FTD and LBD F 85% Age 85.6 ± 5.8 y	Nursing Home (Switzerland)	Change in light conditions: 2 conditions An 8-week individually timed dawn–dusk simulation (DDS) in which polychromatic white LED lighting gradually changed light level with constant CCT: (4000 K), followed by 8 weeks without the DDS. Order semi-randomized between two groups (n=10) (Photometer)	8 weeks (17 weeks in fall and winter)	Be: agitation; social behavior+; verbal interaction* DF: independence in daily life activities; ADL+ MF: alertness*; memory+ Mo: cheerfulness*; mood both * and + QoL: quality of life; well-being* ReAc: Rest-activity rhythms and sleep (many parameters)	5 Visual analogue scales* NOSGER+ Be: CMAI DF: CADS QoL: QUALID ReAc: wrist-actimetry	- Significantly better mood (VAS) and greater cheerfulness upon awakening during the second 4 weeks with DDS (DDS2) compared to no DDS2. -The younger subgroup (<86, n=10) had better mood in DDS1 and DDS 2 (compared to no DDS2). -No statistically significant impact of DDS on NOSGER; CADS; CMAI; QUALID. -Neither circadian nor sleep parameters were significantly influenced by DDS.

Leung et al (2020) ⁶⁴	Empirical study; QDS (3/5)	n=40 residents with dementia (observation) n=96 residents with mild (44.8%)- moderate (55.2%) dementia (survey) F 79.2% (survey) Age all > 65 y; 78.1% over 81 y (survey)	8 Care and Attention Homes (Hong Kong; SAR China)	Existing light conditions Satisfaction level with indoor light was measured (survey). Remark about glare due to poorly shielded lighting lamps (Survey)	NA 10–12 am observation	DF: limited mobility Mo: negative emotion; positive emotion; loneliness ReAc: sleep disturbance	DF, Mo, ReAc: DEMQOL and Dementia Care Mapping	Pearsons correlations: -Negative emotion and loneliness had significant negative relationships with indoor light. -Positive emotion was positively correlated with indoor light. -Sleep disturbance had significant negative interactions with indoor light. Multiple regression analysis: -Positive emotion was positively predicted by indoor light. -Sleep disturbance was negatively associated with indoor light. -Loneliness was negatively predicted by indoor light.
Martin et al (2000) ⁵¹	Descriptive cross-sectional study; QDS (3/5)	n=85 residents with mild-severe AD; F 68.5%; Women significantly older than men M age 82.5 (SD = 7.6) y.	5 Nursing Homes (USA)	Existing light conditions M level of light exposure daytime: 476 lux (SD = 1551, range = 18–12,900 lux, median = 131 lux), M number of minutes of exposure >1000 lux was 19.6 minutes per day (SD = 37.2, range = 0–201 minutes, median = 3.6 minutes). (Actillum)	NA (3 days per person over a 4-year period)	Be: circadian agitation rhythms	Be: ABRs; Actillum	-Higher levels of illumination exposure during the night was significantly associated with agitation throughout the day and night. -Exposure to more minutes of light over 1000 lx during the night was significantly associated with later agitation rhythm peaks. -There was no significant relationship between amount of light during the day and agitation.

Mobley et al (2017) ⁵²	Instrumental case study; MMS (4/5); QS (5/5); QDS (0/5)	n=9 residents with moderate-severe dementia and n=6 certified nursing assistants (observations), n=3 CNAs (e-survey); F residents NR; age: 84–100 y	I Dementia Special Care Unit of a Nursing Home (USA)	Existing light conditions Artificial lighting was exclusively provided by ceiling-mounted fluorescent fixtures, which caused flooring glare. There appeared o opportunity to adjust lighting levels within the unit to reduce glare or help balance residents' circadian rhythms and sleep patterns. (Spatial inventory with photo documentation)	NA (10 weeks; January–March: 6 am–9 pm)	Be: environmental adaptation-coping behaviors Be: environmental maladjustment-stress behaviors	Be: quantitative and qualitative data were collected through a spatial inventory, staff e-survey, and behavioral observations in the unit's public spaces	- Daylighting (including views provided by windows) were found to foster adaptation-coping behaviors. -Certified nursing assistants described problems with sun-setting behaviors, although none were observed during researcher observations.
Münch et al (2017) ⁴²	Between-subjects study; QNRS (5/5)	n=89 residents with severe dementia: AD (50), MD (20), VD (11), FTD (5), PD (2), KS (1); F 65.2%; M age = 78.4 ± 9.0 y	I Nursing Home (Switzerland)	Change in light conditions: 2 conditions At first: a DLS and SLS group. DLS: max. ≈ E _v = 1000 lx from 10:30 am–2:30 pm at eye level sitting; combining 2700 and 6500 K during the day. Producing max. 6000 K. SLS: ≈ 500 lux; 2700 K. Because there was no statistical difference in individual light exposures (in lx) of the activity-light watches between the participants with the dynamic or conventional lighting during daytime, ultimately a high light exposure group (HLG average > 417 lx) and a low light exposure group (average < 417.24 lx); 8 am–6 pm were researched. (Spectroradiometer; activity-light watches)	8 weeks; October-December 2012	Be: agitation DF: independence of daily life activities Mo: subjective emotions QoL: quality of life ReAc: sleep; activity	Be: CMAI DF: CADS Mo: OERS QoL: QUALID ReAc:Daily 24-h measurements with activity-light watches	DLS vs SLS: -No significant differences in CMAI; CADS; OERS. HLG vs LLG - No significant differences in CMAI; CADS. -Significantly more pleasure and higher general alertness. -Pleasure significantly higher in the morning and anger in the evening. -QUALID significantly higher. -No significant difference for sleep latency; sleep end; sleep fragmentation. -Significantly later bedtimes, less time in bed; later sleep time. Gender-specific HLG vs LLG: -Men in HLG had significantly higher activity than men in LLG and women in HLG. -Higher daytime light exposure significantly predicted increase in amplitude in men.

Table 3 Characteristics of Light

Light Level (Illuminance) in lux (lx)	CCT in kelvin (K)
Very low intensity <50	Warm (white) light 2700–3200
Low intensity 50–200	Neutral (white) light 3200–4200
Moderate intensity 200–400	Cool (white) light 4200–6200
Standard intensity 400–600	Very cool (blue) light 6200–9500
High intensity 600–1000	Extremely cool (blue) light >9500
Very high intensity >1000	

Notes: These light levels can be measured horizontally or vertically.

Abbreviation: CCT, correlated color temperature.

physically nonaggressive behaviors.⁴⁶ In addition to agitation assessed by staff caregivers with the CMAI, the study of Barrick et al²⁷ also used direct observations of research personnel to evaluate agitation. Analyzing these observations, nursing home participants with moderate dementia were significantly more agitated under all three bright light conditions (7–11 am, 4–8 pm and all day 7 am–8 pm) than in standard light conditions. Therefore, Barrick et al²⁷ noted that very high-intensity cool light may even exacerbate agitation. An individually timed light intervention simulating a natural pattern of dusk and dawn did not have an effect on agitation.⁴⁷

Most studies regarding existing light conditions (n=5; 71.4%) did not find a relationship between light during the day and sets of challenging behaviors.^{48–52} However, one of these studies investigating agitation rhythms found a relationship of agitation and very high-intensity light during the night.⁵¹ Participants with more minutes of exposure to very high-intensity light during the night displayed their agitation later in the day. They also found that exposure to higher light levels during the night resulted in experiencing some agitation throughout the day and night, with no consistent periods without agitation. Possible sources of the nocturnal light exposure were lights being left on in the bedrooms or participants wandering over to a brightly lit nurses' station.⁵¹

Six articles reported on one or more distinct challenging behaviors, namely anxious behaviors, apathy, pacing, restless behavior, wandering behavior and withdrawn behavior.^{43,53–57} Only two of these studies (33.3%) found the behaviors to have a significant relationship with indoor light. These quantitative descriptive studies conducted in existing light conditions investigated physically active challenging behaviors. The concerned studies reported significantly less wandering⁵³ or pacing,⁵⁴ when light levels were low, which is contrary to findings in similar light conditions on sets of challenging behaviors.^{58,59}

Two studies investigated a direct influence of light on positive behaviors, namely adaptation-coping and social behavior. A mixed methods study found that indoor daylight improved adaptation-coping behaviors. Residents seemed to orient strolling behaviors toward areas with increased daylight and frequently paused to look through the glass in two exit doors.⁵² Using a crossover design, a dawn–dusk simulation did not produce significant effects on social behavior.⁴⁷

Indirect Influence of Light on Behavior

Six studies reported on the relationship of indirect aspects of light exposure and sets of challenging behaviors. Most studies (n=4; 66.7%) found no significant temporal aspects regarding sets of challenging behaviors. They did not find any significant effects in these behaviors before, during or after sunset, nor for any parts of the day, different days of the week, daylengths, months or seasons.^{27,51,52,60}

With regard to sundowning behavior, the results depended on the perspective the observations were made from. Whereas care professionals mentioned that persons with dementia showed (more) challenging behaviors around sunset or in the evening,^{52,59,61} none of these behaviors were observed during researchers' observations.⁵² Furthermore, two quantitative descriptive studies that specifically focused on the timing of these challenging behaviors and used researcher assessments, found no significant proof of these behaviors during or after sunset either.^{51,60} Bliwise et al⁶⁰ stated, therefore, that these disruptive behaviors might occur with identical frequency throughout the day, but might have more impact on the nursing staff later in the day. The study focusing on agitation rhythms showed a substantial amount of variation in these rhythms.⁵¹ This study identified only two persons with dementia (2.4%) having an agitation peak at sundown.

Daily Functioning

Studies investigating the impact of indoor light on daily functioning of persons with dementia focused on independence in activities of daily living (ADL), aspects of food intake and, mobility or falls. A randomized controlled trial (RCT) examining the effectiveness of a long-term intervention (up to 3.5 years) of high-intensity neutral light showed that the ADL in the intervention group decreased significantly less compared to the control group.⁴³ Two studies using different, but short-term (4 and 8 weeks) light interventions during the day did not produce

significant effects on ADL compared to baseline⁴⁵ or the control group.⁴² In the study of Münch et al,⁴² the actual 24-h light exposure of persons with dementia was measured using activity watches with a light sensor. This study, comparing the influence of a dynamic lighting system to standard lighting, did not find any significant differences in the average daily light exposure between the groups. After dividing the sample into a high light and a low light group, based on their actual light exposure, the researchers did not find any significant differences in ADL either. A short-term dawn–dusk light intervention (8 weeks) also did not have a significant impact on ADL.⁴⁷

Regarding food intake, beneficial effects of light have been found. A cross-sectional study, examining the influence of existing light conditions, showed a significant negative association of indoor light with food intake difficulties during dinnertime, but not during lunchtime.⁶² An intervention with improved lighting and table setting contrast during breakfast, lunch and dinner increased 3-day caloric intake of almost all participants.⁶³ This before–after study also showed higher functioning during meals.

Investigating the relationship of light and falls, a cross-sectional study using an environmental assessment tool (Table 2) found that light glare was significantly correlated with a higher risk of falls, while light intensity and light evenness were not.⁴⁸ A quantitative descriptive study found that satisfaction with indoor light had no significant correlation with limited mobility.⁶⁴

Mental Functions

Seven articles reported on different kinds of mental functions, including disturbances of consciousness, spatial orientation, cognition, memory and engagement. No significant effects were found of the two very different light interventions on disturbances of consciousness compared to the control condition.^{56,57} Studies in existing light conditions demonstrated indoor light being an important aid for spatial orientation of persons with dementia.^{52,61,65,66} Observations showed that poorly lighted areas were avoided by people with dementia, thus creating overcrowding in other areas.^{61,65} In a qualitative study, men were observed to urinate in the “slop hopper” because, unlike the toilet areas, this area was easily visible with the lights on and it looked like a toilet.⁶¹ As mentioned in the behavior section, persons with dementia also seemed to orient strolling behaviors toward areas with increased daylight.⁵² An observational study showed that light level significantly predicted the capacity of residents with

dementia to find their way in small-scale group homes, where the light level tended to be lower than in more traditional nursing homes.⁶⁶ These group homes had a larger number of corridors that relied heavily on artificial lighting, Staff knowing their way around and unaware of the importance of light for residents in finding their way around, forgot to switch on the lights and the defunct bulbs made these corridors, even in the middle of the day, very dark.

A long-term intervention with high-intensity neutral light during the day resulted in a significant decrease of cognitive deterioration in the intervention group compared to the control group.⁴³ Concerning memory, no significant impact was found of a dawn–dusk simulation.⁴⁷

When investigating engagement while offering stimuli, researchers hypothesized that because of common vision problems persons with dementia would benefit from bright light, and their engagement would be adversely affected by dark surroundings.⁶⁵ Data, however, showed the contrary, quality of engagement (attention and attitude) was significantly more positive in normal light than in bright light. Nonetheless, duration of engagement was significantly more positive when light was normal than in a dark room.

Mood and Emotions

In all three light intervention studies, depressive symptoms, measured by the Cornell Scale for Depression in Dementia⁶⁷ were significantly improved.^{43–45} However, these light interventions differed considerably in source, color, intensity as well as in duration. A long-term lighting intervention showed a significant decrease in depressive symptoms in the intervention group compared to the control group.⁴³ In a before–after study, a 4-week light intervention significantly decreased depressive symptoms during the intervention period compared to baseline, but the difference lost significance 4 weeks post-intervention.⁴⁵ In the third study, the daylight exposure of the intervention group was increased over a period of 12 weeks.⁴⁴ Every morning the participants of the intervention group were taken to a communal room within 3 meters of a daylit window. The control group was taken to a similar sized area indoors under typical electrical lighting conditions without daylight. This resulted in the daylight intervention group showing a significant decrease in depressive symptoms compared to an increase in the control group. Significant group differences were also found for participants with a probable baseline major depression (CSDD > 10; n=9). The intervention subgroup (n=5) had

a significant reduction in symptoms, comparable to an effective pharmacological treatment.

Five articles reported on the relationship between light and negative affective mood. Two very different light interventions (neutral high-intensity light and extremely cool standard light) yielded no beneficial effects.^{43,57} In a cross-sectional study (n=160) with existing light conditions, persons with dementia who spent many hours in low light levels in their bedrooms showed significant more signs of a negative affective mood, yet no associations were found with light in the living and dining room, where light levels were considerably higher.⁶⁸ As far as negative subjective emotions (anger, sadness and fear) were concerned, no significant differences were found comparing a high light and a low light group.⁴² In a quantitative descriptive study, loneliness and negative emotion had significant negative relationships with satisfaction with indoor light, which in turn was a significant predictor of loneliness.⁶⁴

Positive affective mood was investigated in four very different light conditions and mostly yielded positive results.^{42,47,64} Persons with dementia in a high light group showed significantly more pleasure and higher general alertness than those in a low light group.⁴² However, an intervention with high-intensity neutral light during the day did not produce significant effects on positive affective mood nor on self-esteem in comparison with a control group.⁴³ An individually timed dawn–dusk simulation exposure (DDS) for older adults with dementia significantly produced better mood and greater cheerfulness upon awakening in the second 4-week period of the DDS compared to the second 4-week period without DDS.⁴⁷ Only the relatively younger subgroup (<86 years; n=10) expressed a better mood earlier, namely in the first 4 weeks of the DDS compared to the first 4 weeks without DDS, suggesting that the response may need more time to manifest with higher age. In a quantitative descriptive study, positive emotion, including cheerfulness, was positively predicted by satisfaction with indoor light of persons with dementia.⁶⁴

Quality of Life

We found results suggesting that daytime light affects the quality of life of persons with dementia in long-term care facilities. Two studies in nursing homes reported a significant positive relationship between light and quality of life of persons with dementia.^{42,68} Measuring the light levels in different rooms (bed room, dining room and living room), the quality of life was positively correlated

with the light level of the dining room.⁶⁸ This large cross-sectional study (n=160) found that persons with dementia spending many hours in low light levels in their bedrooms showed more signs of a negative affective mood, which is an element of quality of life. In a between-subjects study (n=89), quality of life was also higher in the high light than in the low light group, but not in the dynamic lighting group when compared to the conventional lighting group.⁴² As mentioned before, this study found no statistical differences in actual light exposure between the dynamic and conventional lighting group. A large cross-sectional study (n=194) in assisted living facilities using an environmental assessment tool found no significant correlation between quality of life and light intensity, light glare and light evenness.⁴⁸ Finally, DDS had no effect on quality of life either.⁴⁷

Rest–Activity

The following results concern studies examining the influence of light on rest–activity during the day (n=8), on rest–activity at night (n=12) and on circadian rest–activity rhythms (n=11).

Rest–Activity Daytime

In general, the light interventions had no effect on daytime rest–activity, apart from the results for some specific subgroups. However, studies in existing light conditions predominantly found a positive correlation between light and activity. Three studies using light interventions of (very) cool light with different light levels during the day showed no significant influence of light exposure on daytime rest–activity of persons with dementia.^{28,42,45} However, two of these studies did find significant relationships for specific characteristics, namely severity of dementia and gender. First, in persons with (very) severe dementia, exposure to high-intensity light between 4 and 8 pm was associated with a significant increase in daytime sleepiness.²⁸ Second, men in the high light group had significantly higher activity (from 10 am to 8 pm) than men in the low light group and women in both groups.⁴² A quantitative descriptive study (n=12) in existing light conditions found no relationship between light level and activity during the day.⁶⁹ However, this sample may have been too small to reach significance. In addition, the sample consisted only of women. Two larger cross-sectional studies (n=77;⁷⁰ n=66⁷¹) in existing light conditions found a positive relationship between (the peak of) light exposure and (the peak of) activity during the day.^{70,71} One of these studies

found, “persons with dementia whose peak of light exposure occurred early in the day also had an early peak in activity.”⁷¹ Thus, for most of these individuals, the peak of light exposure preceded the peak of activity. This study also showed that persons with dementia who spent more time in very high light levels (>2000 lx) had significantly later activity peaks.

Rest–Activity Nighttime

Most studies (n=7; 70%; MMAT-score ≥ 3) that examined nighttime rest–activity variables found significant influences of light.^{42,43,45,64,71–73} However, these results were difficult to compare, because of the variety in light conditions and the use of many different – not always clearly defined – sleep variables.

With regard to nocturnal restlessness, no significant influences were found from different light conditions.^{43,47,69} However, a 3-year retrospective longitudinal study did find a specific combination of day length and cloud amount to have an influence on nocturnal restlessness of persons with dementia in nursing homes.⁷³ In this study, nighttime activity (indicating nocturnal restlessness) of persons with dementia was significantly higher on cloudy short days than on cloudy long days or on clear short days.

Most studies, including three intervention studies, investigating awakenings at night found no significant influence of light exposure.^{42,43,47,69,70} In contrast, a high quality cross-sectional study in existing light conditions found persons with dementia who had been exposed to higher light levels during the day had significantly fewer awakenings during the night.⁷¹ Two other studies researched indoor light in a different way. Making efforts to reduce noise and light levels during incontinence care at night, led to a significant decrease in the number of awakenings (related to “light only” and “light and sound”) in the intervention group compared to the control group.⁷² Satisfaction with indoor light was another factor associated with less sleep disturbance.⁶⁴

There was no light condition that significantly influenced sleep onset latency.^{42,43,45,70} In a between-subjects study, the high light group showed significant later bedtimes and spent less time in bed than the low light group.⁴² Most of the studies investigating sleep efficiency (including a long-term RCT)^{43,47,70} did not yield any significant results. Only a before–after study showed a significant increase in sleep efficiency as well as in sleep quality during an intervention with very cool light of moderate

intensity.⁴⁵ Two light intervention studies, the aforementioned study and an RCT, yielded significant positive results on total sleep time during the night. In this RCT, an intervention with high-intensity neutral light increased total sleep duration by 10 minutes per year for up to 3.5 years.⁴³ Studies in existing light conditions and a DDS had no influence on total sleep time during the night.^{47,69,70}

24-Hour Rest–Activity Rhythms

Using the following circadian rest–activity parameters, only a few studies found an influence of light on circadian rest–activity rhythms, such as interdaily stability, intradaily variability, circadian amplitude, 24h-sleep and 24h-activity time. Interdaily stability is used to compare the day-by-day regularity of the 24-hour sleep–wake pattern.⁴⁵ Intradaily variability represents the frequency and extent of transitions between periods of rest and activity during the day.⁴⁵ One repeated measurement study found favorable results for interdaily stability (an increase) and intradaily variability (a decrease) during a light intervention with very high-intensity light, but only when removing persons with severe visual deficiencies from the sample.⁷⁴ Five later published studies exploring different light conditions (not including high-intensity light), yielded no significant results for these two variables,^{42,45–47,69} not even when excluding persons with severe visual deficiencies.^{42,45} One of these studies originally used high-intensity dynamic lighting, but compared circadian rhythms only between the high light and low light group (not being equal to the dynamic and conventional lighting group).⁴²

The definitions used for circadian amplitude, amplitude or relative amplitude for the rest–activity cycles are largely, but not entirely, similar. They all represent a difference between the means of the most active 10-hour period (“day”) and the least active 5-hour period (“night”) in the average 24-hour pattern.⁷⁵ No significant relationships were found between light exposure and amplitude,^{42,46,47,69,74} not even if the studies excluded people with severe eye diseases.^{42,74} The between-subjects study of Münch et al,⁴² however, has found a gender-specific susceptibility, noting that “higher daily light exposures significantly predicted an increase in relative amplitude only for men.” As far as total activity is concerned, this study found no overall greater activity in the high light than in the low light group. In a cross-sectional study in existing light conditions, daytime light

exposure was positively correlated with 24-h activity, but not with 24h-sleep time.⁷⁰

When other parameters were used to investigate 24-hour rest–activity rhythms (phasor magnitude; tympanic temperature), two intervention studies both using very cool light, but of different intensity, found significant evidence for improved circadian rhythms.^{45,56} Nonetheless, an intervention of extremely cool high-intensity light, using tympanic temperature, did not find any notable circadian effects.⁵⁷

Bodily Functions

Both studies (an RCT⁴³ and a clinical trial⁷⁶) showed no increase of adverse effects of the intervention group compared to the control group. Instead, the RCT, a long-term intervention study using high-intensity neutral light significantly lowered the ratings on five items: irritability, dizziness, headache, constipation and inability to sleep.⁴³ No significant effects were found on the prescription use of psychotropic medication.⁴³ Visual performance was only touched upon in one article. In this study, six caregivers (35.3%) indicated by questionnaire that the visual performance of their clients improved after installing (dynamic) lighting systems.³⁰

Discussion

This systematic literature review demonstrated that researchers have investigated many different health outcomes in relation to the potential effects of indoor light on older persons with dementia living in long-term care facilities. Behavior was the most researched health outcome, and within this area researchers focused almost exclusively on challenging behaviors. Only two before–after studies in which (very) cool light of moderate intensity was provided showed a significant decrease in agitation.^{45,46} We found no conclusive evidence that periods with less light due to the sunset or to dark seasons caused sundowning behavior. Further, there was no convincing evidence that high-intensity light positively influenced the circadian day–night rhythm, despite a much-cited study from the 1990s showing promising results.⁷⁴ Although many studies showed a beneficial influence of daytime light on nighttime sleep and activity, for each of the variables, it often concerned a single study. In contrast, a 3-year longitudinal study found nocturnal restlessness to be related to a specific combination of day length and cloud amount, namely cloudy short days,⁷³ while other light conditions showed no influence. We found that

dynamic lighting did not improve day–night rhythm, nor did it improve quality of life.^{30,42,46} However, in one before–after study dynamic lighting decreased agitation.⁴⁶ There were some indications that indoor light exposure during the day positively affected the quality of life of older persons with dementia in long-term care facilities.^{42,68} There are quite strong indications that indoor light can help reduce depressive symptoms and that incident daylight may play an important role in this effect. None of the included studies focused on light for good vision, although light showed to be an important aid for spatial orientation in older persons with dementia.^{52,61,65,66}

Non-Seasonal Depression

Non-seasonal depression is common in older adults with different types of dementia, causing personal (and professional) caregiver distress.^{77–80} Nevertheless, only three studies researched the influence of indoor daylight and lighting on depression in long-term care facilities. These light intervention studies showed promising beneficial effects on depression, sometimes even comparable to an effective pharmacological treatment.^{43–45} An equally small number of research evaluated the treatment of depression in this population using light boxes.^{81–84} The intervention study with the longest treatment period (8 weeks) had significant treatment effects on depression, regardless of the severity of dementia.^{83,84} A recent study using aggregated data of three light intervention methods (floor luminaires, light boxes, and light tables) showed a beneficial influence on depressive symptoms as well.⁸⁵ Despite the limited body of research, these combined results confirm the applicability of light to treat and possibly prevent non-seasonal depression among older adults with dementia in long-term care facilities. Probably, indoor daylight and lighting can play an important role in ameliorating depressive symptoms in a more comfortable way than light boxes and with fewer side effects than pharmacological treatment.

Dynamic Lighting

Imitating natural light indoors was found in the use of dynamic lighting systems. Following up on claims from suppliers, long-term care facilities are installing dynamic lighting systems to improve the well-being and circadian rhythms of older adults with dementia.³⁰ Contrary to the industry's compelling claims, research on this topic is still in its early stages and far from conclusive.¹⁰ The term

dynamic lighting itself does not provide much clarity. Dynamic lighting scenarios can differ in terms of light intensity, CCT and the timing and duration of both elements. The two dynamic lighting interventions in our review differed in light intensity and CCT, but were similar in duration of light exposure.^{42,46} One of these studies measured the actual daytime light exposure with individual light sensors, and showed that the average daily light exposure did not differ significantly between the group with dynamic lighting and the group with standard lighting.⁴² Despite the fact that both studies were executed in darker seasons, persons in the standard lighting group could go outside or sit in the vicinity of daylight windows, so their light exposure was effectively dynamic too. A review on the rationale for dynamic lighting found several reasons for applying dynamic lighting scenarios, which call for different requirements of the dynamic lighting system.¹⁰ Using dynamic lighting to entrain the biological clock, for instance, might require another lighting scenario than the ones needed for executing different tasks or activities. Developing effective dynamic lighting scenarios for the different needs of older adults with dementia in long-term care facilities still requires further new high-quality research. For now, the results for this particular study population are inconclusive.

Limitations and Strengths

This review focused on a clearly defined target group, which enabled us to unravel specific influences of indoor light on older persons with dementia living in long-term care facilities. In addition, we focused on indoor daylight and lighting and excluded studies that (also) focused on other methods of light administration, such as light boxes and light visors, which have different (dis)advantages and characteristics. By combining the results of quantitative, qualitative and mixed-method studies we were able to include a wide range of research focusing on a broad spectrum of health outcomes. Because of this heterogeneity, however, it was not feasible to undertake a meta-analysis. This heterogeneity also made it difficult to find strong evidence and draw unambiguous conclusions. Additionally, several included studies lacked relevant light data, which hindered comparing and interpreting the results. Finally, though we focused on studies of older adults with dementia, persons with different types of dementia can possibly react differently to light.

Recommendations for Future Research and Practice

Although ensuring good quality and quantity of light may support older adults with dementia to (more) independently perform everyday activities, only a few of the included studies have focused on this topic. A review on the use of the physical environment to support everyday activities for people with dementia showed overall ADL scores, orientation in space and eating and drinking to be the most frequently researched everyday activities.⁸⁶ The studies included in our review focused precisely on these everyday activities. We recommend further research on the influence and requirements of light to support persons with dementia in performing these and other important everyday activities, such as carrying out hobbies, communicating and getting dressed.

Second, we recommend future research to include accurate descriptions of the light conditions, since almost every study was missing essential elements. To compare and interpret the results, it is imperative that researchers give a clear description of the lighting equipment, the light measurements, the building or room and the exposure to the different light sources, including daylight.^{10,38} Therefore, it is necessary to develop and use consolidated strategies for the description and assessment of both static and dynamic lighting.¹⁰

Third, future randomized studies are needed to obtain stronger evidence of (very) cool light of moderate intensity to reduce agitation. In addition, further research is needed to clarify the most effective indoor light conditions to prevent or alleviate depressive symptoms. In doing so, we strongly suggest to research the influence of indoor daylight exposure for more than 2 hours per day. We also recommend to clarify which light conditions significantly influence quality of life.

Finally, we recommend both management and care professionals of long-term care facilities to increase their awareness of the potential impact and risks of inadequate light in the daily life of older adults with dementia. Many included articles reported insufficient light conditions in long-term care facilities. A higher quality and quantity of light can support residents to perform everyday activities, to feel better and to prevent unpleasant situations, such as falls and feeling unsafe in dark places. Moreover, this greater quality and quantity of light is also needed for the task performance of (aging) care professionals, for example, to reduce errors in administering medication.⁸⁷

Conclusions and Future Directions

Overall, we found moderate evidence for the influence of indoor light on the health of older persons with dementia living in long-term care facilities. The most promising results of indoor light concerned the reduction of depressive symptoms and the facilitation of spatial orientation. With regard to challenging behaviors, we only found indications for a very specific light intervention to decrease agitation. Further research is needed to corroborate these results in which it is important to describe the characteristics of the light conditions more clearly. No conclusive evidence was found for the influence of indoor light on sundowning behavior, nor on circadian rest–activity rhythms. To date, the research on dynamic lighting has yielded little evidence of its efficacy and has not been sufficiently researched among this study population. Based on our findings, we recommend long-term care facilities to raise awareness of the increased lighting needs of older adults with dementia and the potential beneficial effects of indoor light on health.

Clinical Interventions in Aging

Publish your work in this journal

Clinical Interventions in Aging is an international, peer-reviewed journal focusing on evidence-based reports on the value or lack thereof of treatments intended to prevent or delay the onset of maladaptive correlates of aging in human beings. This journal is indexed on PubMed Central, MedLine, CAS, Scopus and the Elsevier

Submit your manuscript here: <https://www.dovepress.com/clinical-interventions-in-aging-journal>

Bibliographic databases. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
