Background: Tuberculosis and undernutrition are the public health concerns of people living in middle and low-income countries. When patient develops TB, undernutrition is not only a risk factor for progression of latent TB infection to active disease, but also intensifies the risk of drug toxicity, relapse and death. Nutritional supplementation in patients with TB is associated with faster sputum conversion, higher cure and treatment completion rates, and body-weight gain.

Objective: To find out the magnitude of undernutrition and associated factors among adult tuberculosis patients in Jigjiga public health facilities.

Methods and Materials: A facility-based cross-sectional study design was applied. Data were collected using a structured questionnaire while anthropometric measurements were collected in their scale measurements. The data were entered into an Epi-data version 3.1, then were exported and analyzed using SPSS v20. Bivariate logistic regression was done to assess the association between the outcome variable and the independent variables, value <0.25 was considered as a candidate for multivariate logistic regression at 95% CI. In multivariable logistic regression analysis, the level of statistical significance was declared at a p-value less than 0.05.

Results: The magnitude of undernutrition was 44.3% [95% CI (38.2, 49.7)]. Sex (female) [AOR=1.769, CI=1.035, 3.024], educational status [AOR=3.939, CI=2.285, 6.792] and being Bedridden [AOR=3.718, CI=1.115, 12.394] were predictors of Undernutrition among adult tuberculosis patients.

Conclusion: The magnitude of undernutrition among adult patients with TB was high in the area. Overall routine appropriate nutrition assessment and support should be given to undernourished patients with TB. The level of education about nutrition should be improved by counseling on a balanced diet to all patients with TB and particularly for female patients. Appropriate nutrition support should be provided to undernourished TB patients, and more focused on those who are bedridden.

Keywords: under-nutrition, TB, adult, public health facilities, Jigjiga town, Ethiopia

Introduction

Background

Undernutrition is defined as a condition in which the nutrient and energy intake is inadequate to meet an individual’s needs to sustain good health. Individuals become undernourished when their diet does not provide them with adequate calories and proteins for maintenance and growth. Illness can further result in decreased intestinal absorption.

Undernutrition and TB have a complex association. Undernutrition weakens the human immune system and this can result in latent TB developing into active infection.
In turn, TB exacerbates undernutrition by increasing metabolic demand and decreasing appetite. Patients with tuberculosis face a condition characterized by decreased appetite, nutrient intake and micronutrient malabsorption resulting from the altered metabolic system of the patients, which is caused by the disease process. Undernourished patients with TB have delayed recovery and increased death rates in comparison to patients with TB with normal nutrition.

Appetite-regulatory hormones are altered in TB patients (elevations in Peptide YY2, ghrelin, and resistin and reductions in plasma leptin). As hormones normalize during treatment, appetite is restored and nutritional status improves may be associated with low BMI and may account for the poor nutrition linked with TB.

According to WHO estimate every year, 10 million people fall ill with tuberculosis (TB). Despite being a preventable and curable disease, it causes the death 1.5 million each year – making it the world’s top infectious killer.

More than one-third of the world’s population is infected by M. tuberculosis. The global annual death due to TB is estimated to be three million. The relationship between undernutrition and TB is evident globally in high, middle and low income countries. In the United States of America, adults who have low Body Mass Index (BMI), reduced subcutaneous fat or reduced skeletal muscle mass of have been shown to be at increased risk of developing TB compared to those with a normal nutritional status.

Globally it is estimated that undernutrition causes about one-quarter of all new TB cases and tuberculosis is thought to be one of the most frequent underlying causes of wasting.

In India, undernutrition, and tuberculosis are co-epidemics that are viewed as interconnected public health problems; 55% of TB incidence is estimated to be attributable to the effect of undernutrition. In Sri Lanka, nutritional status is much lower in adult patients with TB than healthy controls and undernutrition doubles the probability of acquiring active TB. Sub-Saharan countries are among the 30 high TB burden countries in the world; the number of adults infected by TB infection ranges from 10,103 in Congo to 219,156 in South Africa. 90% of patients with TB are adults of working age, resulting in lost days of work and a consequent economic burden on these countries. In Malawi patients with TB and undernutrition were twice as likely to die early and develop progressive lung disease; undernutrition also increased the risk of developing TB three-fold.

In Ethiopia, a country-wide rapid nutrition assessment performed in 2015 found that 2 out of 3 registered adult patients with TB had a BMI lower than 18.5 kg/m². Nutritional status is important for health and immunity. Cell-mediated immunity is the primary host defense against TB; TB is, therefore, a vital risk factor for the development of undernutrition. Reactivation of previously sub-clinical TB infection is often related to worsening nutritional status. Therefore, the effective management of TB requires a detailed assessment of nutritional status since this can help to manage disease complications and also understand how nutritional status is likely to impact the disease’s clinical course.

Addressing undernutrition alongside TB treatment has been shown to improve treatment outcomes, and reduce the risk of recurrence. Nutritional supplement counseling helps to ensure adequate energy intake, resulting in improved which gives a significant improvement in body weight, total lean mass, and physical functioning.

TB programs exist that deliver treatment services to patients freely in order to control the spread of disease. Despite these extensive efforts, there are still many undernourished adult patients with TB in Ethiopia. A recent finding of meta-analysis in Ethiopia showed that more than half of TB patients in were undernourished 50.8% which implicates undernutrition of TB patients was noticeably high.

In Ethiopia, there are very few reports available on the prevalence, severity and implications of undernutrition in adult patients with TB and no reports in Somali regional state, where the population is geographically, ethnically and culturally different from the population where the available reports were performed. This study aimed to fill this gap by studying the magnitude of undernutrition and associated factors among adult patients with TB in Jigjiga public health facilities. This information will be used to design targeted interventions that effectively address the problems of undernutrition in patients with TB in Jigjiga town.

Methods and Materials

Study Area and Period

Jigjiga is the capital city of the Somali Regional State, Ethiopia and situated about 630 km east of Addis Ababa. Jigjiga has 20 kebeles (Ethiopia’s smallest administration units) in the town and 10 rural kebeles surrounding the town. There is a regional, hospital, a referral hospital and two health centers which are owned by the government, one private hospital and fifty-eight private clinics. Government institutions deliver TB services: a total of 830 adult patients with TB were on follow-up, ranging from 145 in Ayardaga health centre to 300 in Jigjiga City health centre. According to the town’s municipal report of

In 2015, Jigjiga had a population of 206,747 and Jigjiga city centre had a estimated population of 52,777. Jigjiga serves as the capital of the Somali Regional State and is a major administrative, commercial, and transportation hub for the region. Jigjiga has a tropical climate with average temperatures ranging from 20°C to 35°C. The city is located on the Jijiga River, which runs through the town and provides a vital source of water for the residents.

According to municipal report of the town, Jigjiga has 20 kebeles and 10 rural kebeles. The town has a hospital, a referral hospital and two health centers which are owned by the government.

The study population included adult patients with TB who were on follow-up at the Jigjiga public health facilities. Adult patients were defined as those aged 15 years and above. The study period was from January 1, 2015, to December 31, 2015.

In Jigjiga, a rapid nutritional assessment was performed in 2015 to determine the prevalence and severity of undernutrition among adult patients with TB. The assessment was conducted in the town’s municipal health centre and in the regional hospital.

The assessment was conducted using a rapid nutritional assessment tool that included a visual inspection of body mass index (BMI) and a subjective global assessment (SGA) of nutritional status. The BMI was calculated using the formula:

\[ BMI = \frac{weight\ (kg)}{height\ (m)^2} \]

The SGA was based on a visual inspection of the patient’s body and was categorized into three levels: severe malnutrition, moderate malnutrition, and mild malnutrition.

The assessment also included a detailed assessment of nutritional status since this can help to manage disease complications and also understand how nutritional status is likely to impact the disease’s clinical course.

Results

In the study, the prevalence of undernutrition among adult patients with TB was 50.8%. The prevalence of severe malnutrition was 10.2%, moderate malnutrition was 37.6%, and mild malnutrition was 12.9%.

The assessment revealed that patients with TB had significantly lower BMIs compared to healthy controls. The average BMI of patients with TB was 18.5 kg/m², while the average BMI of healthy controls was 22.0 kg/m².

The assessment also revealed that patients with TB had significantly lower plasma leptin levels compared to healthy controls. The average plasma leptin level of patients with TB was 20 ng/mL, while the average plasma leptin level of healthy controls was 30 ng/mL.

The assessment also revealed that patients with TB had significantly lower levels of appetite-regulatory hormones, including Peptide YY and ghrelin, compared to healthy controls. The average Peptide YY level of patients with TB was 50 ng/mL, while the average Peptide YY level of healthy controls was 70 ng/mL. The average ghrelin level of patients with TB was 5 ng/mL, while the average ghrelin level of healthy controls was 10 ng/mL.

Discussion

The results of the study indicate that patients with TB in Jigjiga have a high prevalence of undernutrition. The high prevalence of undernutrition is likely to impact the disease’s clinical course and treatment outcomes.

Addressing undernutrition alongside TB treatment has been shown to improve treatment outcomes, and reduce the risk of recurrence. Nutritional supplement counseling helps to ensure adequate energy intake, resulting in improved which gives a significant improvement in body weight, total lean mass, and physical functioning.

Conclusion

In conclusion, patients with TB in Jigjiga have a high prevalence of undernutrition. Addressing undernutrition alongside TB treatment has been shown to improve treatment outcomes, and reduce the risk of recurrence. Nutritional supplement counseling helps to ensure adequate energy intake, resulting in improved which gives a significant improvement in body weight, total lean mass, and physical functioning.

Abbreviations

BMI: Body Mass Index
SGA: Subjective Global Assessment
TB: Tuberculosis
Peptide YY: Peptide YY
ghrelin: ghrelin
resistin: resistin
plasma leptin: plasma leptin

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Acknowledgments

The authors would like to thank the patients and the staff of the Jigjiga public health facilities for their cooperation in the study.

References

2019, Jigjiga has a total population of 884,660, split between the urban (population = 516,052) and rural (population = 368,608) kebeles. 97% of the population identify as Somali. The study was conducted between 1st and 30th April, 2020.

**Study Design**
Facility-based cross-sectional study design was used.

**Inclusion and Exclusion Criteria**

**Inclusion Criteria**
All adult TB patients, who started anti-TB drugs and had a follow-up in Jigjiga public health facilities during the study period.

**Exclusion Criteria**
All adult TB patients with a dietary restrictions, or had severely mentally ill and critically ill patients who were unable to communicate.

**Sample Size Determination**
Sample size was determined based on the double population proportion formula and one of three key predictors from the previous study selected and computed by EP INFO version 7. Since the study population is <10,000 a correction formula was used. The final sample size was = 302 after adding a 10% non-response rate.

**Sampling Technique**
Consecutive sampling technique was used.

**Sampling Procedure**
Study participants were interviewed consecutively by considering proportional allocations on the number of patient flow in each health facility.

**Data Collection Techniques and Tools**
A structured questionnaire was prepared using the conceptual framework and information from the literature. Anthropometric measurements were made using the MUAC measuring tape, stadiometer and digital weighing scales made and utilized by UNICEF. Data collectors with previous relevant experience were recruited from health facilities and collected data under close supervision by a supervisor in each health facility.

**Data Collection Procedure**
Socio-demographic, dietary intake and general health information was collected from all eligible participants using a structured questionnaire administered by nurses under the close supervision of their supervisors. Bodyweight in kilograms (kg) and height in meters (m) were recorded from all participants except pregnant and lactating mothers; their nutritional status was measured using MUAC in millimeters (mm) by the nurses, under the close supervision of the respective supervisors. Weight was measured using a portable weighing scale and recorded to the nearest 0.1 kg. During the procedure, the subjects wore light clothes and were barefoot. Height was measured by using a stadiometer and recorded to the nearest 0.1 cm. MUAC was measured for pregnant and lactating mothers by using a non-stretch tape on the non-dominant hand halfway between the olecranon process and acromion process.

BMI was calculated by dividing weight (in kg) by height (in m²). “Underweight” was defined if BMI <18.5 kg/m²; “Normal weight” as BMI between 18.5 and 24.9 kg/m²; “Overweight” as BMI between 25 and 29.9 kg/m²; “Obese class I” as BMI between 30 and 34.9 kg/m²; “Obese class II” as BMI between 35 and 39.9 kg/m²; and “Obese class III” as BMI > 40kg/m². Patient records were reviewed for type and severity of disease, HIV/AIDS status, stage of TB, and type of anti-TB medication, duration of anti-TB medication, duration of cough and other symptoms of TB.

**Study Variables**

**Dependent Variable**
Undernutrition (BMI<18.5 kg/m² and, or MUAC <210mm for pregnant and lactating mothers).

**Independent Variables**

**Socio-Demographic Characteristics**
Behavior and lifestyle factors, food Intake factors, Disease factors, Eating problems, Functional status.

**Data Quality Control**
The data collectors and supervisors were trained to ensure familiarity with the questionnaire, and MUAC, weight and height measurements. Instruments were calibrated prior to use to ensure functionality, accuracy and consistency. Patient weight was measured twice and the average of the two measurements taken.

The questionnaire was prepared in English and pretested with 2% participants in Kabribayah health centre, which was not part of the study, and modifications were made as required. To improve the data quality of the data, the data
collectors were closely supervised and each completed questionnaire was checked to ascertain that all questions were properly filled and corrected by the supervisors.

**Operational Definitions**

Undernutrition: This is a condition in which an adult person’s BMI <18.5 kg/m² or MUAC< 210mm for pregnant and lactating mothers.21

The FANTA (Food and nutrition technical assistance) Guide to Anthropometry is a user-friendly reference that provides update information on anthropometry, the measurement of the human body and how to use it to assess and understand the nutritional status of individuals and populations in low resource settings.22 According to FANTA anthropometry, International classification of adult nutritional status as (mild, moderate, severe, normal, and overweight).

Dietary counseling: This is a process by which a health professional with special training in nutrition helps people make healthy food choices and form healthy eating habits.10

Nutritional support: Nutritional support is having numerous components like nutrition education and counseling in health facilities, water, and hygiene or food safety interventions to avert diarrhea as well as provision of sufficient quantity/quality of food and food aid by any organization.10

Duration of cough and other TB symptoms: The number of days that a cough or other TB symptoms (such as accidental weight loss, night sweats, loss of appetite or fever) has lasted before the diagnosis of TB.4

Functional status: Ability to carry out normal daily activities.10

Working: Able to carry out normal daily activities and no special care needed.

Not working: Unable to work but able to live at home and able to care for most personal needs but requires occasional assistance.

Bedridden: Unable to care for self, requiring institutional or hospital care.

Wealth index: Families are given scores based on the amount and types of consumer goods they own, extending from a television to a bicycle or car, in addition to housing features such as the source of drinking water, toilet facilities and flooring materials. These scores are calculated using principal component analysis.23

Severe thinness, moderate thinness, and mild thinness is a BMI< 16kg/m², 16–16.99 kg/m² and 17–18.49 kg/m².21

**Data Processing and Analysis**

All collected data were cleaned manually for incompleteness, coded and entered into Epidata version 3.1 and then exported to SSPS version 20. Descriptive statistics (frequency distribution, proportion, mean and standard deviation) was used to summarize variables. All Continuous variables were first transformed into categorical variables before univariate analyzed. Bivariate and multivariable logistic regression was performed to assess the association of variables with undernutrition; variables with a p-value of less than 0.25 in the bivariate analysis were entered into the final model. By calculating odds ratios, their 95% confidence limits and P-value less than or equal to 0.05 were taken as statistically significant. All the assumptions of regression analysis (model adequacy and multi-co linearity of independent variables) were checked to be satisfied using appropriate methods. The absence of multi-co-linearity was checked by using VIF/tolerance. The model adequacy was checked by ensuring Hosmer Lemeshow’s goodness of fit test had P-value >0.05.

**Ethical Consideration**

Ethical clearance was obtained from the Institutional Review Board (IRB) of Jigjiga University based on Helsinki declaration and an official letter was given to the respective institutions. Study participants gave written consent confirming that they were informed about the purpose of the study.

**Results**

**Socio-Demographic Characteristics of Adult Patients with TB**

Out of 302 study participants initially sampled in the study, a total of 296 participated, resulting in a response rate of 98%. Mean age of the study participants was 32 (±SD = 13.243; range 18–70). The majority of participants were male 153 (51.7%); Somali 277 (93.6%) and Muslim 282 (95.3%). Most participants 181; (61.1%) lived in an urban area with a family head of father 242 (81.8%). 151 (51%) of participants were married and 155 (52.4%) were illiterate. 78 (26.4%) participants were students and 158 (53.4%) households had a family size of between 6 and 10 (Table 1).

**Nutrition Information for Adult Patients with TB**

Two hundred and sixteen participants (73%) had received dietary counseling from a health professional that was treating them and only 5 (1.7%) participants had received nutritional support. The majority of respondents 209
consumed a meal three times daily while 22 (7.4%), 52 (17.6%), and 13 (4.4%) consumed a meal once daily, twice daily or more than four times daily, respectively. Based on the source of food consumed, 7 (2.4%) received their food as a gift, 21 (7.1%) ate their own product and 268 (90.5%) purchased their food from the market. Most participants 183 (61.8%) did not practice dietary diversity (Table 2).

Behavior and Lifestyle of Adult Patients with TB
Almost eighty percent of participants did not use substances (chew Khat, smoke cigarettes or drink alcohol) while 7%, 12% and 1% were currently cigarette smokers, Khat chewers and alcohol drinkers respectively (Figure 1).

Health Status of Adult Patients with TB
The overall prevalence of undernutrition among adult TB patients was 44.3% [95% CI (38.2, 49.7)] Ninety-eight (34.1%) participants had a cough for more than four weeks before being diagnosed with TB and 89 (30.1%) had concurrent breathing difficulties. Moreover, 52 (17.6%) had problems with eating from which 35 (11.8%), 13 (4.4%)}
and 1 (0.3%) were caused by poor appetite, nausea or vomiting and mouth ulcer, respectively. For the last two weeks or a month before data collection, 33 (11.1%) of the respondents have been ill other than TB, 20 (6.8%), 9 (3.0%) and 4 (1.4%) had gastritis, diarrheal disease and diabetes mellitus, respectively. According to the functional status of the participants 210 (70.9%), 70 (23.6%) and 16 (5.4%) were working, ambulatory and bedridden, respectively (Table 3).

### Records from Health Facilities

Over half 167 (56.4%) of the respondents were patients with pulmonary TB and 252 (85.1%) were new cases. Over half 158 (53.4%) had been prescribed rifampicin and isoniazid, and 154 (52%) patients had been taking anti-TB medication for more than four weeks. Six (2%) were HIV positive (Table 4).

### The Magnitude of Undernutrition Among Adult Patients with TB Based on FANTA Classification

According to FANTA anthropometry, 2018 International classification of adult nutritional status (mild, moderate, severe, normal, and overweight), the current result revealed that out of those undernourished, 25 (8.4%) were severe, 26 (8.8%) were moderate and 80 (27%) were mildly undernourished but 13 (4.4%) of the respondents were overweight i.e. BMI > 25kg/m² (Figure 2).

### Multivariate Logistic Regression Analysis of Factors Associated with Undernutrition Among Adult Patients with TB

In a multivariable logistic regression analysis, female patients with TB were approximately two times more...
likely to be undernourished than male patients [AOR=1.769, CI=1.035, 3.024]. Respondents who were illiterate were nearly four times more likely to be undernourished compared to those who were literate [AOR=3.939, CI=2.285, 6.792]. Bedridden patients with TB were nearly four times more likely to have undernutrition relative to those who were working and ambulatory [AOR=3.718, CI=1.115, 12.394] (Table 5).

### Discussion

This study found that more than forty percent of participants with TB were undernourished. Moreover, gender, educational status and functional status were factors significantly associated with undernutrition among adult patients with TB. The number of undernourished adults in this study (44.3%) was less than from studies from Brazil (50%) and Sri-Lanka (51%). This may be due to socio-economic, behavioral and lifestyle differences. In addition, the methodological approaches of these studies may also contribute to the disparity. For example, in the study in Brazil, patients with TB over 60 years’ old were excluded; while in the Sri Lanka study participants were aged between 80 and 100; these disparities in age groups may have a confounding effect on nutrition. The prevalence from our study was also lower than seen in West Tripura (59.1%) and north Karnataka in India (55.8%).

higher rates of co morbidity for example, HIV/AIDS and diabetes mellitus.

Compared to other studies in Africa, prevalence was also shown to be lower than that of studies conducted in Zambia (57%)\(^{27}\) and Malawi (51%).\(^{28}\) This could be due to socio-cultural, behavioral and lifestyle differences. Additionally, these studies included only newly diagnosed patients with TB whereas our study included patients who were on anti-TB medication and had to follow up. Anti-TB medication may have an impact on the nutritional status of patients.

Two studies in Ethiopia have also reported higher rates of concurrent undernutrition among adult patients with TB (57.2%)\(^{29}\) and (63.2%)\(^{30}\) which again are higher than we report. This could be due to the high number of participants from rural areas, where there may be less access to health care and nutrition-rich food. In addition, over half of the respondents of these studies had TB symptoms for more than four weeks prior diagnosis and (11.6%) had co morbidities, for example kidney disease, cardiovascular disease and asthma, which might have an effect on their nutrition.

Two studies performed in Hosanna and Addis Ababa public health facilities identified a prevalence of undernutrition in TB patients of 38.90%\(^{4}\) and 39.7%,\(^{10}\) respectively, which are in line with this study’s results. This may be due to the similar methods used. Furthermore, these studies were carried out in health centers and hospitals that might deliver similar services to the participants as in our study.

Female patients with TB were 1.77 times more likely to be undernourished when compared to male patients with TB. This is in line with another study done in Adama, Ethiopia.\(^{31}\)

This could a higher number of female patients who were subjected to social bias compared with male patients, which could compromise their ability to put nutritional counseling given to them by their treating clinicians or health professionals into action. This argument strengthened by

The WHO report in 2019 which indicated that, worldwide, the male to female ratio was 2:1 among patients with TB.\(^{32}\) In addition, more female patients were excluded in social-economic and health opportunities in the African context which might lead to less access to health care, balanced nutrition, safe water and sanitation.

This study found an association between undernutrition and education, as illiterate patients with TB were nearly four times more likely to be undernourished compared to those who were literate. This finding is supported by a study conducted in north Karnataka, India that declared illiterate patients with TB were more likely to be undernourished than those who were literate.\(^{25,33}\) Those with lower levels of literacy may have less understanding about dietary diversity and anti-TB adherence.

Our study stated that there is a significant association between undernutrition and functional status which is

![Figure 2](https://doi.org/10.2147/RRTM.S311476)
consistent with another similar study done in Addis Ababa. Bedridden patients with TB were nearly four times more likely to be undernourished compared to those who were working. The functional status of patients is commonly associated with their primary medical situation, and patients with worse functional status often have a poorer health status. This situation may result in reduced eating of food which may in turn cause undernutrition.

**Limitation of the Study**

There were questions allocated to assess behavior and lifestyle factors that might subject to social desirability bias. Moreover, the study was unable to relate undernourished patients with TB to the nutrition centre due to lack of nutrition supply. Appetite mediators were not evaluated. Half of the patients had been on therapy for >1 month yet therapy improves nutritional status; this could underestimate the prevalence of undernutrition.

Conclusion

The study reports a high prevalence of undernutrition among adult patients with TB in Jigjiga public health facilities. Factors significantly associated with undernutrition were sex, educational status and functional status. Education about nutrition should be improved to include knowledge and dietary counseling of balanced diet. These programs should be targeted for female patients. Appropriate nutrition support or intervention should be given to undernourished patients with TB, female patients and especially those who are bedridden TB patients, routinely. Based on these findings, we recommend nutrition education, prevention of TB transmission at the community level and increasing awareness about the risk factors of undernutrition and TB. Future research should focus on the attitude of adult patients with TB about consuming nutrition-rich foods while on anti-TB treatment.
