**Background:** Ischemic stroke is one of the leading causes of mortality and disability worldwide. Following stroke, there is secondary neuroinflammation that promotes further injury. Identifying the long non-coding RNA (lncRNA) involved in neuroinflammation after cerebral ischemic stroke will promote the discovery of potential therapeutic targets.

**Methods:** We identified differentially expressed genes from genome-wide RNA-seq profiles of mice with focal ischemia using Gene Ontology Term Enrichment, Kyoto Encyclopedia of Genes and Genomes, and Gene Set Enrichment analyses. Immune cell infiltration deconvolution, protein-protein interaction network construction, and co-expression network analyses were also used to screen lncRNAs. In further experiments, lncRNA *Neat1* knockdown animal models were developed by intraventricular injection of the antisense oligonucleotide before performing middle cerebral artery occlusion (MCAO). An enzyme-linked immunosorbent assay was performed to measure the level of cytokines. Hematoxylin-eosin staining and immunohistochemical staining were used to observe the changes in morphology.

**Results:** Enrichment analysis revealed that differential mRNAs induced neuroinflammation after MCAO. Immune deconvolution showed that the proportion of microglia gradually increased while monocytes decreased within 24 h. We identified six hub lncRNAs (*Neat1*, *Gm10827*, *Trp53cor1*, *Mir670hg*, *C730002L08Rik*, and *Mir181a-hg*) that were highly correlated with activated-microglia mRNAs ( $\text{cor} > 0.8$ ). We found that *Neat1* had the highest correlation coefficient with pro-inflammatory factor mRNA levels. In vivo experiments demonstrated that *Neat1* had abnormally high expression after MCAO. Knockdown of *Neat1* could significantly alleviate brain damage by reducing the number of activated microglia and reducing their release of proinflammatory cytokines.

**Conclusion:** We identified inflammation-associated lncRNA *Neat1* as crucial, which means it is a potential target for ischemic stroke treatment.

**Keywords:** bioinformatics, lncRNA *Neat1*, ischemic stroke, MCAO, microglia, neuroinflammation

## Introduction

Ischemic stroke is one of the leading causes of disability and death worldwide; its pathological processes are typically associated with inflammation, oxidative stress, blood-brain barrier disruption, apoptosis, autophagy, and eventually neuronal cell death in the brain.<sup>1-3</sup> To remove cellular debris and restore tissue homeostasis,<sup>4</sup> damage-associated molecular patterns were extensively released with inflammatory cytokines and microglia activated in to the damaged area.<sup>5</sup> The normally immune-privileged brain environment is consequently exposed to systemic responses that

Email doctor\_duanzj@163.com;  
2517079319@qq.com

further aggravate the immune responses and cause secondary brain damage.<sup>6</sup> Therefore, controlling post-ischemic inflammation is considered a potential therapeutic target in ischemic stroke.

Long non-coding RNA (lncRNA), defined as transcripts longer than 200 nucleotides with little protein-coding capacity, constitutes a large proportion of the transcriptome.<sup>7</sup> Accumulating evidence has shown lncRNA plays a pivotal role in the pathophysiological processes of ischemic stroke injury. For instance, antisense RNA to INK4 locus (*ANRIL*), metastasis-associated lung adenocarcinoma transcript 1 (*MALAT1*), maternally expressed 3 (*MEG3*), and *1810034E14Rik* have been validated as affecting cell inflammation, apoptosis, cell death, and angiogenesis in ischemic stroke.<sup>8–11</sup> However, the lncRNAs that regulate inflammation in the acute phase of ischemic stroke have been studied very little.

In this study, we identified the lncRNA nuclear paraspeckle assembly transcript 1 (*Neat1*) associated with inflammation after ischemic stroke in mice. *Neat1* and its human ortholog *NEAT1* assemble paraspeckles and maintain their structural integrity.<sup>12,13</sup> The paraspeckle is a specific type of nuclear body in the interchromatin space whose function remains unknown.<sup>14</sup> *Neat1* has two transcript isoforms; ie, *Neat1\_1* (3190 nt) and *Neat1\_2* (20,771 nt)<sup>12</sup> (Supplemental Figure 1A). In contrast to the *Neat1\_2* isoform, which has been observed in low abundance in various organs of adult mice, *Neat1\_1* exhibits high expression throughout the brain (Supplemental Figure 1B). Our study on *Neat1* was more specifically dealing with *Neat1\_1*.

We used bioinformatics and functional analysis to screen lncRNA candidates that promote ischemic inflammation. Furthermore, we verified the target lncRNA *Neat1* first and then further clarified its pro-inflammatory biological function through loss-of-function studies.

## Materials and Methods

### Genome-Wide Transcriptomic Data Processing

We downloaded high throughput raw data SRA files (GSE112348) from the NCBI Gene Expression Omnibus (GEO, <https://www.ncbi.nlm.nih.gov/gds/>). Twelve samples from both healthy and post-ischemic male C57BL/6 mouse cortices were created at different reperfusion time-points (6 h, 12 h, or 24 h) with Illumina sequencing. The SRA Toolkit converted each SRA to the FASTQ format.

Quality control processes included adapter trimming, removal of low-quality reads, and removal of short reads with fastp software.<sup>15</sup> Clean paired-end reads were aligned to the mouse reference genome GRCh38 using HISAT2.<sup>16</sup> Samtools was then used to convert the aligned sam files to sorted bam files. Gene expression for each sample was quantified by counting the number of uniquely mapped reads with featureCounts.<sup>17</sup> For annotation, we annotated gene symbols via Mus\_musculus.GRCh38.99.gtf (<http://asia.ensembl.org/>), and those without gene symbol reads were dropped. The flowchart diagram for this study is represented in Figure 1A.

### Screening of Differentially Expressed Genes (DEGs)

Normalization and DEGs analyses were performed with the Deseq2 R package.<sup>18</sup> The duplicate gene rows were removed and the mean value was taken as the expression value. All q-values were used as the false discovery rate (FDR) to correct the statistical significance of multiple groups ( $p < 0.05$ , FDR  $< 0.05$ ) and absolute log2 fold change  $\geq 2.0$  (mRNA) or  $\geq 1.0$  (lncRNA) was considered significant.

### Functional and Pathway Enrichment Analyses

Gene Ontology (GO), Kyoto Encyclopedia of Genes and Genomes (KEGG) and Gene Set Enrichment Analysis (GSEA) were used to uncover functional annotations through the Bioconductor R package clusterProfiler<sup>19</sup> or DAVID website tool (<https://david.ncifcrf.gov/>). GO was used to describe the set of gene functions along with three aspects: biological process (BP), cellular component (CC), and molecular function (MF). The KEGG and GSEA databases were searched for pathways at the significance level cutoff  $p < 0.05$ . The interaction network of BP terms was constructed with Cytoscape software<sup>20</sup> and ClueGO plugin.<sup>21</sup> The protein-protein interaction (PPI) network was analyzed using the STRING functional protein association network (<https://string-db.org>).

### lncRNA-mRNA Co-Expression Network

We obtained a mRNA gene symbol list for regulating microglial activation from the MSigDB website (<https://www.gsea-msigdb.org/>) to construct the lncRNA-mRNA co-expression network. We used seq-immuCC<sup>22</sup> to estimate the relative proportion of different immune cell types in samples. Each differentially expressed lncRNA was

**Figure 1** Differential genes involved in the pathophysiology of MCAO. **(A)** Outline of the workflow in the present study. **(B and C)** Principal component analysis results of mRNAs and lncRNAs. **(D)** The number of mapped, annotated, protein-coding and lncRNA genes expressed during dataset procession. **(E)** Heatmap of DEGs between Sham and MCAO at various time points. **(F and G)** The Venn diagram shows the intersection of mRNA and lncRNA DEGs at different time points. **(H and I)** Volcano plot shows the distribution of log fold change and adjusted *p*-value for mRNAs and lncRNAs; indicated genes represent the top of both up-regulated and down-regulated genes.

calculated with the Pearson correlation test using the expression value of these mRNAs. For each pair of lncRNA-mRNA analyzed, only the absolute value of a correlation  $\geq 0.8$  and  $p < 0.01$  pair was considered a strong correlation (either positive or negative).

## Animals

Male C57BL/6 mice (8 weeks, weight, 21–25 g) were purchased from Charles River Laboratory (Charles River Laboratories, Inc., Beijing, China). Animals were housed under controlled temperature and humidity conditions (22

$\pm 1^{\circ}\text{C}$ ; 40–60%) under a 12/12-h light/dark cycle with food and water ad libitum. The animal experiments were approved by the Ethics Committee of Zhujiang Hospital (Approval Number: LAEC-2020-012) and performed in accordance with the National Institutes of Health guidelines for the care and use of laboratory animals.<sup>23</sup>

## Silencing of the lncRNA *Neat1*

*Neat1* knockdown was performed using 2'-OMe antisense oligonucleotides (ASOs) synthesized by RiboBio (RiboBio Co., Ltd., Guangzhou, China). ASOs (5'-GGAAATCATAGAGGACAGGC-3') or Scrambled control (5'-GAAGAAGTACGAAGTGACGC-3') were delivered to the groups through intraventricular administration. Mice were anesthetized with 1% pentobarbital sodium (60 mg/kg) by intraperitoneal injection and then fixed in a stereotaxic frame. A skin incision was made and puncture points were made at x (1.5 mm from the sagittal suture), y (−2.0 mm from the bregma), and z (2.5 mm depth). ASO-*Neat1* (2 nmol, 2  $\mu\text{L}$ ) or ASO-scramble (negative control, ASO-NC) was injected into the intraventricular once a week for 2 weeks before middle cerebral artery occlusion (MCAO).

## MCAO Model

Two weeks after injection, MCAO procedures were performed according to previous studies.<sup>24</sup> Briefly, mice were anesthetized with 2% isoflurane in oxygen for 3 min and maintained with 1.0 to 1.5% isoflurane in 70%  $\text{N}_2\text{O}$  and 30%  $\text{O}_2$  using a small-animal anesthesia system (Vet Equip, Pleasanton, CA, USA). Body temperature was maintained at a constant  $37.5^{\circ}\text{C}$  during surgery with a heating pad. A midline neck incision was cut and the left common carotid artery (CCA) and external carotid artery (ECA) were isolated. After temporarily blocking the internal carotid artery (ICA) and CCA, a silicone-coated monofilament (MSMC21B120PK50, RWD Life Science Inc., Shenzhen, China) was inserted via the arteriotomy in the ECA and slowly advanced through the left ICA to reach the origin of the middle cerebral artery (MCA). The monofilament was removed after a 60-min occlusion, and the ECA was ligated permanently. Animals that died of anesthetic procedural problems during surgeries, 12h, or had no neurological deficits after the operation were excluded from the study (Supplemental Table 1). The mouse in the sham group was inserted with a monofilament to occlude the MCA and then the monofilament was withdrawn immediately to restore blood flow.

## Animal Experimental Design

The animal experiments were performed as follows (Supplemental Figure 2). Mice were randomly assigned to different groups according to a previously described method.<sup>25</sup> There were no significant differences in the number or weights of animals in each group.

### Experiment 1

The relative expression level of six lncRNAs associated with activation of microglia were detected by quantitative polymerase chain reaction (qPCR) at 24 h after MCAO. Ten mice were randomly allocated into two groups including the sham and MCAO groups ( $n = 5$ ).

### Experiment 2

For qPCR detection of the time-course of *Neat1* expression levels after MCAO, a total 20 of mice were randomly divided into four groups: the sham group and three MCAO subgroups (at 6 h, 48 h, 72 h after MCAO;  $n = 5$ ).

### Experiment 3

Sixty-four mice were randomly assigned to the four groups, including the sham, MCAO, MCAO + ASO-NC, MCAO + ASO-*Neat1* groups, for the examination with qPCR and an enzyme-linked immunosorbent assay (ELISA,  $n = 5$ ), 2,3,5-triphenyl tetrazolium chloride (TTC) staining ( $n = 5$ ), brain water content (BWC;  $n = 5$ ), hematoxylin-eosin (HE) staining, and immunohistochemical (IHC) staining ( $n = 3$ ).

### Experiment 4

Thirty mice were randomly divided into three groups, including the MCAO, MCAO + ASO-NC, and MCAO + ASO-*Neat1* groups ( $n = 10$ ), to evaluate the effects of knocking down *Neat1* on neurological function and survival in mice post-MCAO.

## Neurological Function Evaluation

Mice were assessed with the Modified Neurological Severity Score (mNSS) test<sup>26,27</sup> at 12 h, 24 h, 48 h, and 72 h after MCAO. Specific criteria for mNSS in mice were scored as shown in Supplemental Table 2. The higher score represents the more neurological severe impairment (normal score, 0; maximal score, 14). Scores were evaluated by two observers who were blind to the mice groups.

## TTC Staining

Mice were sacrificed at 24 h after MCAO and brains were rapidly harvested and cut into five coronal sections (1.5 mm thick each). They were then incubated in a 2%

TTC solution (Sigma-Aldrich, St. Louis, MO, USA) for 30 min at 37 °C and then transferred into a 4% paraformaldehyde solution for 24 h for fixation. The infarction area in each slice was measured with ImageJ software (ImageJ, 1.8.0, NIH, Bethesda, USA) after digital photo capture.

## Brain Water Content Analysis

Brains were removed at 24 h after MCAO. Left and right hemispheres were weighed immediately to obtain the wet weight and were then oven-dried at 75 °C for 48 h to obtain the dry weight. The brain water content percentage was computed as follows: [(wet weight - dry weight)/wet weight] × 100%.

## qPCR

Total RNA was isolated with TRIzol reagent (#15596-026, Invitrogen™ TRIzol™, Thermo Scientific, USA). 1 mg of RNA was used to synthesize cDNA using the RT Master Mix (#RR036A, Takata Bio, Dalian, China). qPCR was performed using SYBR Green real-time PCR analysis with specific primers (Table 1). PCR amplification was performed as follows: 95 °C for 5 min, followed by 40 cycles of 95 °C for 10 s and 60 °C for 60 s. The expression of candidate lncRNAs was calculated using the  $2^{-\Delta\Delta C}$  method and Gapdh as an internal control.

## ELISA

At 24 h post-MCAO, mice were anesthetized and transcardially perfused with phosphate-buffered saline (PBS, pH

7.4, 4 °C). The infarcted hemisphere was harvested immediately and homogenized in 0.9% normal saline 200 mg/mL and centrifuged at 12,000 rpm for 20 min. The supernatant was collected and stored at -80 °C until used further. The concentrations of tumor necrosis factor alpha (TNF-α), interleukin 6 (IL-6), interleukin 1 beta (IL-1β), interleukin 4 (IL-4), and interleukin (IL-10) in brain tissue lysates were analyzed using commercial ELISA kits (#88-7324-22, #88-7064-22, #88-7013-22, #88-7044-22 and #88-7105-22, Invitrogen, Thermo Scientific, USA) according to the manufacturer's instructions. The final concentration of cytokines was determined according to the standard curve of absorbance.

## H&E Staining

Three mice in each group were anesthetized and perfused with PBS (pH 7.4, 4 °C) followed by 4% paraformaldehyde solution (4 °C). The brains were removed and post-fixed in 4% formaldehyde solution for 24 h at 4 °C. After being dehydrated and embedded with paraffin, the samples were cut into 4 μm thick sections. Sections were deparaffinized and then rehydrated in decreasing concentrations of ethanol; they were then stained with H&E solution (#G1005, Servicebio, Wuhan, China) according to the manufacturer's protocols.

## IHC Staining

The deparaffinized and rehydrated coronal sections (4 μm thickness) were prepared as described previously. Endogenous peroxidase activity was quenched using 3% H<sub>2</sub>O<sub>2</sub> for 10 min at room temperature. Sections were then blocked in 5% bovine serum albumin for 20 min and were incubated overnight at 4°C with anti-Iba1 rabbit pAb (1:400; #GB11105, Servicebio, Wuhan, China). Sample slices were then washed with PBS and incubated with biotinylated goat anti-rabbit IgG (1:200; #PV-6001, ZSGB-Bio, Beijing, China) for 15 min at room temperature. Next, brain slices were incubated with horseradish peroxidase-streptavidin reagent for 10 min and developed using diaminobenzidine peroxidase substrate. Images were captured on a bright-field microscope (DM2500, Leica Microsystems, Wetzlar, Germany).

## Statistical Analysis

All statistical analyses were performed using R (version 4.0.2). The volcano plot was plotted with the R package "EnhancedVolcano". Heat maps were drawn with the R package "pheatmap". The GO chord plot was generated

**Table 1** Primer Sequence of qPCR

with the R package “Ggplot”. The survival curves were constructed with R package “survminer”. The Pearson correlation matrix was generated with the R package “corrplot”. The Shapiro–Wilk test was used to test continuous variables for normality. Student’s *t*-test was used for normal distribution variables; Mann–Whitney U rank-sum tests were used for variables that did not follow a normal distribution. Statistical results are presented as the mean ± standard deviation (SD) or standard error (SEM). For all comparisons, a *p*-value <0.05 was regarded as statistically significant.

## Results

### Sequence Data Summary and DEG Analysis

Using the mouse genome (mm10) whole-genome alignment, principal component analysis clustered 12 samples into four distinct populations, in line with the four sample populations from different groups (Figure 1B and C). Data from the sham group and each time point after MCAO were obviously distinguished. A total of 40,972 genes were mapped and 21,933 mRNA genes and 13,180 lncRNA genes, were detected in at least one sample (Figure 1D). Comparing the transcriptome expression of the sham and MCAO groups at different time points and then taking the intersection of DEGs (Figure 1E), a total of 441 up-regulated mRNAs and 72 down-regulated mRNAs and 42 up-regulated lncRNAs and 16 down-regulated lncRNAs were identified (Figure 1F and G). These DEGs were visualized separately in volcano maps (Figure 1H and I). Of note, there were significantly more up-regulated genes than that of down-regulated genes after MCAO.

### GO Term Enrichment and KEGG Pathway Analysis

To explore the biological function of the DEGs, we extracted protein-coding DEGs (Figure 2A) to perform GO term enrichment and KEGG pathway analysis. Up-regulated mRNAs were enriched in the function of immunologic reactions (cell chemotaxis, cytokine activity, and leukocyte chemotaxis) and activating immune cell migration (neutrophil and monocyte); cellular component and molecular function indicated a relation to inflammation reaction (Figure 2B and C). The KEGG pathway analysis results of the DAVID and GSEA showed that the TNF pathway, JAK-STAT pathway, and NFκB pathway were activated (Figure 2D and E). These results showed that the

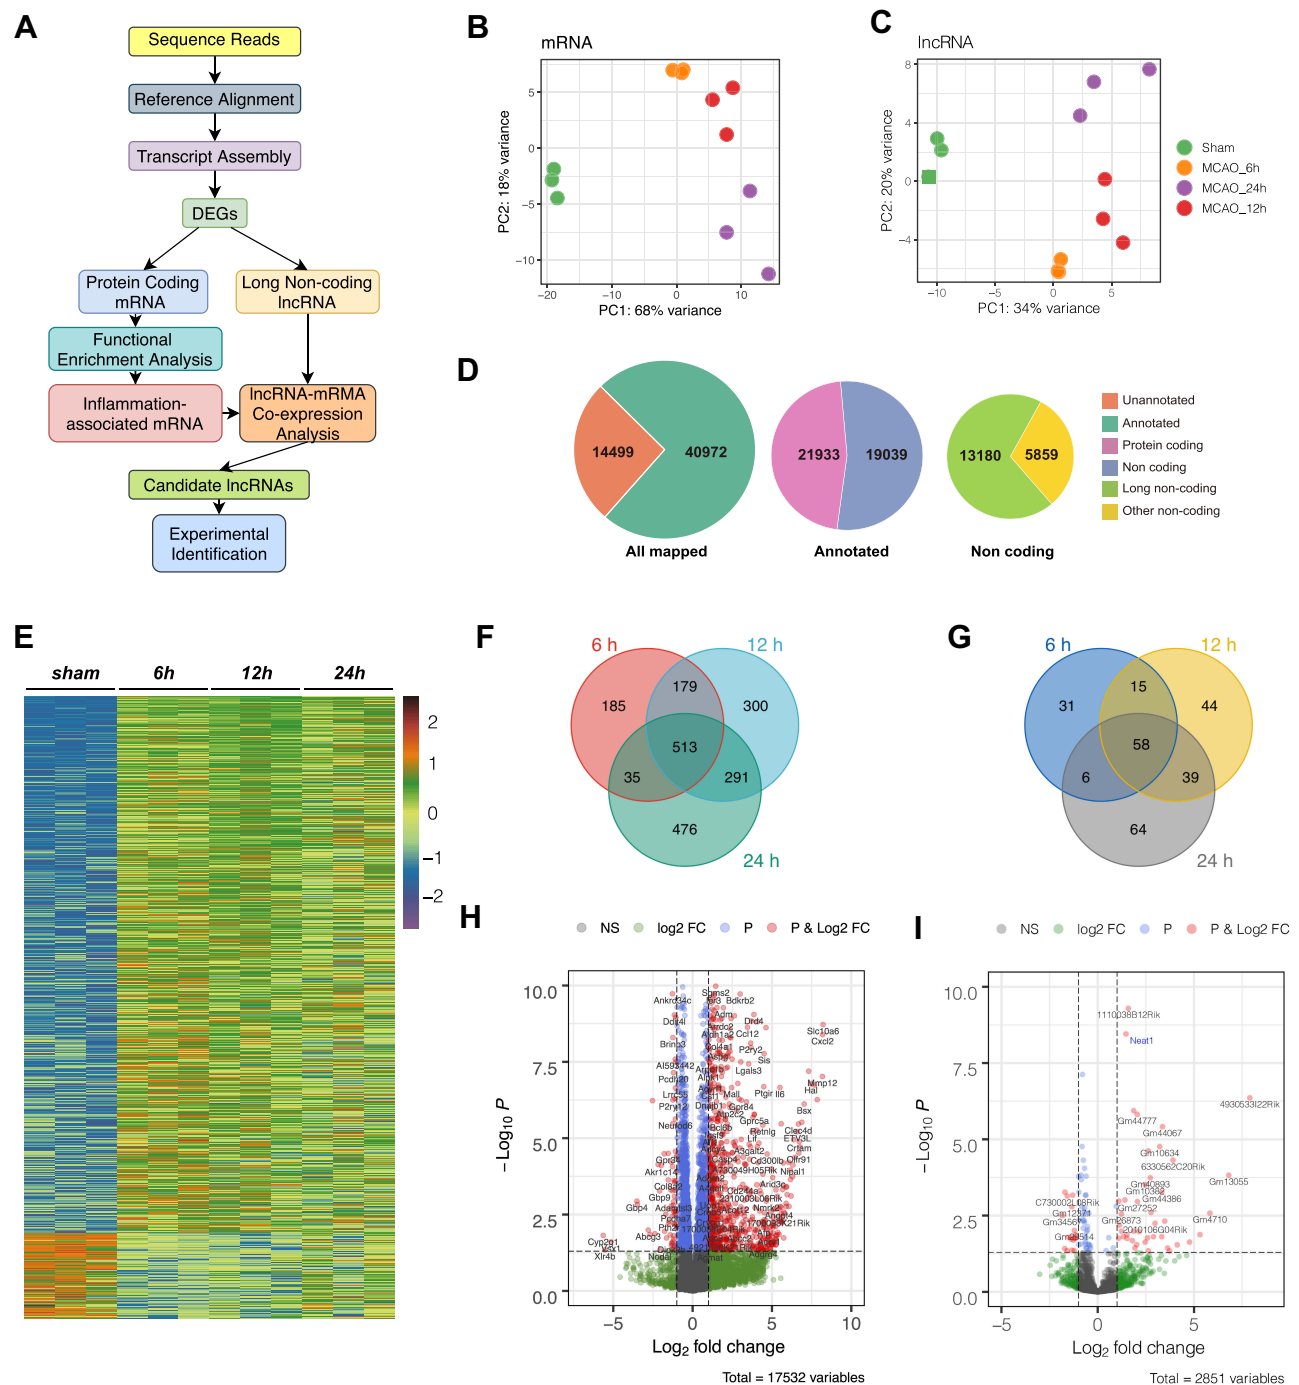

DEGs were involved in inflammatory responses after MCAO.

### Co-Expression Analysis of lncRNA Associated with Inflammation

To identify the lncRNA that regulates inflammation, we first used clueGO to perform network analysis on the enriched GO terms. The results showed that inflammation is closely related to the activation of microglia (Figure 3A). Then we constructed a PPI network with key mRNAs involved in activating microglia (Figure 3B). To further investigate the changes in microglia after MCAO, we applied the deconvolution method to estimate the relative proportion of different immune cell types in mouse cerebral tissue by seq-immuCC.<sup>22</sup> MCAO groups displayed a gradual increase in the microglia proportion following the time course in 24 h. Simultaneously, the proportion of monocytes declined (Figure 3C). Finally, we performed a co-expression analysis on the transcript expression values of these differential mRNAs and differential lncRNAs that activate microglia, and we screened the 23 lncRNAs with the highest correlation coefficients from the matrix of long non-coding DEGs (Figure 3D and E). The top ten hub lncRNAs were found with a high correlation coefficient ( $|cor| > 0.8$ ) to 27 mRNAs of the activated microglia (Figure 3F). The pie chart matrix (Figure 3G) illustrates correlation coefficients between lncRNAs and mRNAs.

### Verification of lncRNAs Related to Microglia Activation

In the early stage of ischemic stroke, activated microglia can secrete a variety of pro-inflammatory factors, promote neuroinflammation and aggravate brain damage.<sup>28</sup> We analyzed the correlation between the expression levels of six candidate lncRNAs and the proinflammatory factor mRNA secreted by microglia. The results showed that *Neat1*, *Gm10827*, *Trp53cor1*, and *Mir670hg* were positively correlated with the expression of proinflammatory factors, while *C730002L08Rik* and *Mir181a-hg* were negatively correlated (Figure 4A). Among them, *Neat1* had the highest correlation with the expression level of inflammatory factors, and the correlation coefficients with IL-6, IL-1β, TNF-α, and NFκB were 0.894, 0.756, 0.868, and 0.929, respectively. To verify these results of co-expression, we established the animal model (mice subjected to 1 h MCAO, 24 h reperfusion) and detected

the RNA expression levels with qPCR. The results showed that *C730002L08Rik*, *Mir181a-1hg*, and *Mir670hg* had no significant differences (Figure 4B, C and F), while *Gm10827*, *Trp53cor1*, and *Neat1* were

significantly increased (Figure 4D, E and G). Combining the results of bioinformatics analysis and qPCR, we decided to study *Neat1* further. Subsequently, we tested the changes in *Neat1* in 6 h, 24 h, 48 h, and 72 h after

**Figure 4** Verification of lncRNAs related to microglia activation after ischemic stroke. **(A)** Analysis of the correlation between six lncRNAs (*C730002L08Rik*, *Mir181a-1hg*, *Gm10827*, *Trp53cor1*, *Mir670hg*, and *Neat1*) and the expression of proinflammatory factors mRNA (*Il6*, *Il1*, *Tnfα*, and *Nfκb*). MCAO (Figure 4H). We observed that *Neat1* expression was maintained at a high level compared to the sham group.

## ***Neat1* Knockdown Ameliorated Ischemic Brain Insult and Reduced Pro-Inflammatory Cytokine Release After MCAO**

To characterize the impact of *Neat1* in experimental stroke in vivo, ASO-*Neat1* was used to knockdown *Neat1* expression in MCAO mice. *Neat1* is localized in the nucleus. The use of lentivirus or adenovirus to interfere with the effect is inefficient.<sup>29</sup> We therefore chose ASO for animal knockdown experiments. First, we examined the knockdown effect of ASO-*Neat1*, as shown in Figure 5A. *Neat1* expression of the ASO-*Neat1* group was significantly downregulated compared with the ASO-NC and MCAO groups. We next rated the neurological severity scores for the mice. The results showed that the neurological function of the mice was impaired significantly, but the ASO-*Neat1* group showed lower function damage compared to the MCAO and ASO-NC groups (Figure 5B). Moreover, during the subsequent 7-day recovery phase, the ASO-*Neat1* group showed better functional recovery and lower mortality (Figure 5C). Furthermore, *Neat1* knockdown mice had less cerebral edema (Figure 5D) and smaller infarct volume in TTC staining (Figure 5E and F). We then investigated whether knockdown *Neat1* regulates the levels of inflammatory factors released by the microglia. ELISAs determined three pro-inflammatory cytokines; ie, IL-1 $\beta$  (Figure 5G), IL-6 (Figure 5H), and TNF- $\alpha$  (Figure 5I); two anti-inflammatory cytokines; ie, IL-4 (Figure 5J) and IL-10 (Figure 5K). Knockdown of *Neat1* reduced MCAO-induced IL-1 $\beta$  and TNF- $\alpha$  proinflammatory cytokine levels and enhanced IL-10 and IL-4 anti-inflammatory cytokines levels. These findings suggested that knockdown of *Neat1* reduces the inflammatory response induced by microglia activation, thereby reducing brain damage.

## ***Neat1* Knockdown Ameliorated Ischemic Brain Tissue Damage and Reduced the Number of Activated Microglia**

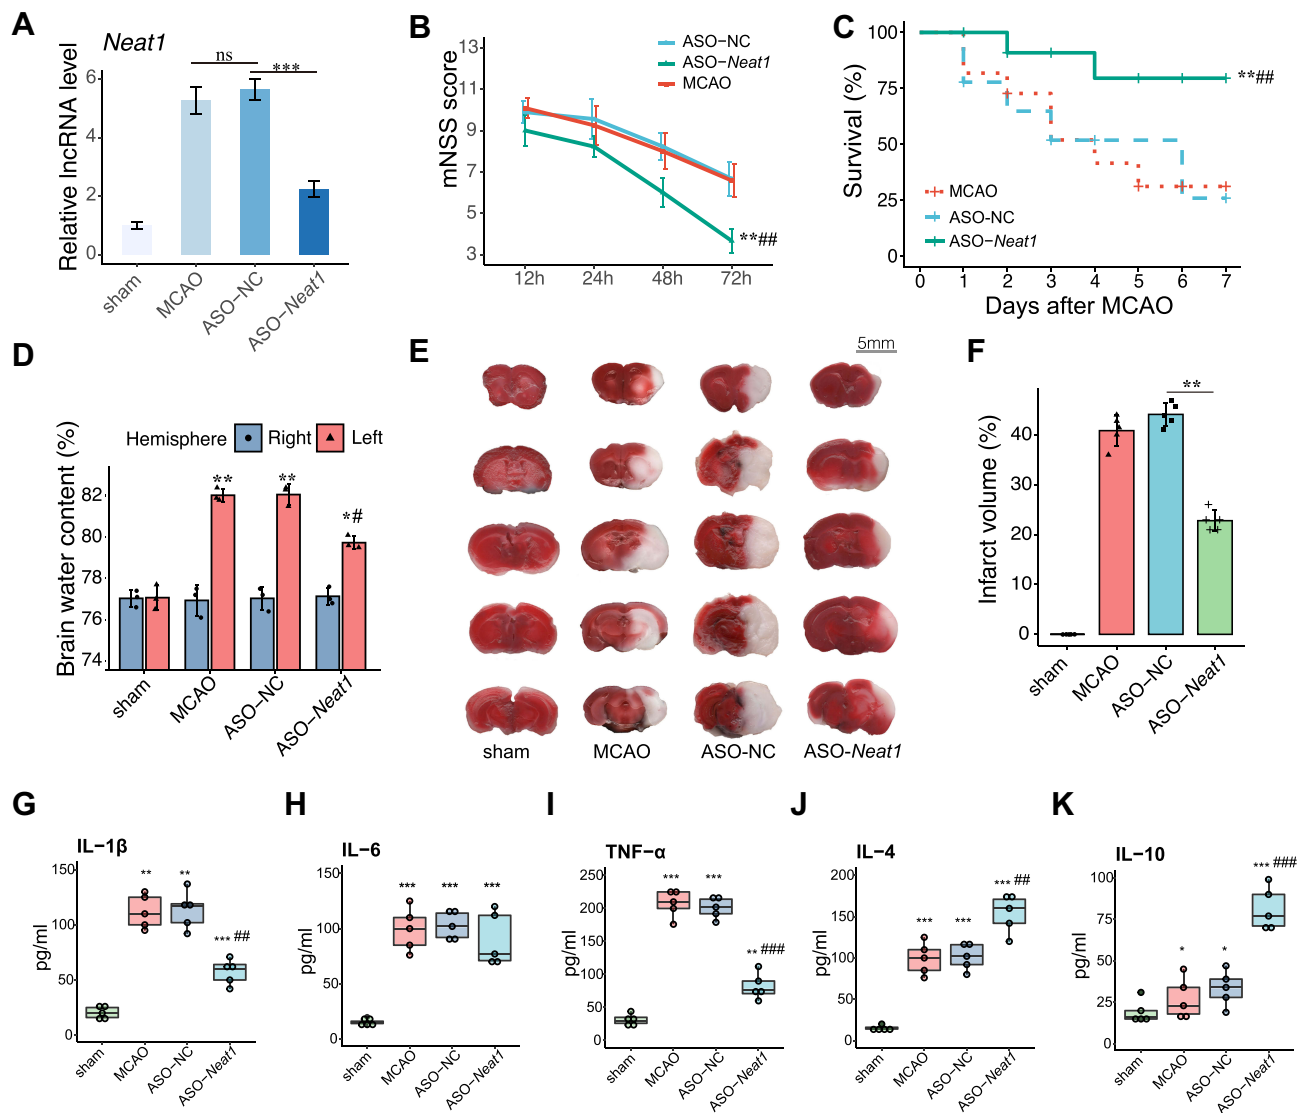

We further observed the pathological changes in the cortex and striatum under a microscope (Figure 6A). Morphological alterations were observed with HE staining. Pyknotic nuclei and vacuolated cytoplasm were markedly reduced in the cortex and striatum of ASO-*Neat1* mice (Figure 6B). Immunohistochemical staining

showed that activated microglia were found in all groups after MCAO. Compared to the sham group, microglia had shorter ramifies and larger cell bodies. Also, there were significantly fewer activated microglia in the ASO-*Neat1* group compared with the MCAO and ASO-NC groups (Figure 6C).

## **Discussion**

Accumulating evidence has indicated that lncRNAs play an essential role in physiological and pathological responses in various diseases.<sup>30</sup> However, until now, few lncRNAs have been studied in ischemic stroke<sup>31</sup> and function in the pathological process of cerebral ischemia remains largely undefined. The rapid development of bioinformatics analysis methods provides an entry point for exploring the biological functions of lncRNA. We applied differential expression, hierarchical clustering, functional GO enrichment, KEGG and GSEA pathway analysis, PPI network construction, immune component deconvolution, and mRNA-lncRNA co-expression network analysis to process and analyze high-throughput sequencing data of ischemic stroke. Our study's major finding is the identification of the inflammation-related lncRNA *Neat1* by mRNA-lncRNA co-expression analysis and subsequent experimental verification. Furthermore, it is the first demonstration that the overexpression of *Neat1* in ischemic stroke is closely related to the activation of microglia in vivo, and *Neat1* knockdown has a suppressing effect on inflammation.

Recently, increasing evidence has indicated there is an inflammatory role for *Neat1* in ischemic stroke. For instance, *Neat1* had a pro-inflammation effect in a BV2 cell oxygen-glucose deprivation/reoxygenation (OGD/R) model and knockdown of *Neat1* reduces microglial activation and inhibits activity of the AKT/STAT3 pathway.<sup>32</sup> These findings are consistent with our research results. However, contrary to previous studies, we used animal experiments to illustrate the anti-inflammatory effects of knockdown *Neat1* on early ischemic stroke. In addition, we first clarified in the transcriptome the dynamics of *Neat1* and microglia at different time points after MCAO by analyzing the cortex sequencing data. Therefore, our study is deeper than and complementary to previous studies. Moreover, a previous study reported *NEAT1* is up-regulated in peripheral blood samples from patients with acute ischemic stroke and is positively correlated with recurrence/death risk.<sup>33</sup> Mice *Neat1* acts as

**Figure 5** *Neat1* knockdown reduced the infarct volume and decreased pro-inflammatory cytokines after MCAO. (A) The expression of *Neat1* was detected with qPCR after ASO-*Neat1* administration. Data are presented as the mean  $\pm$  SEM,  $n = 5$ ,  $***p < 0.001$  versus ASO-NC,  $ns\ p > 0.05$  versus MCAO, Mann-Whitney test. (B) Time-course of modified neurological severity scores. (D) The brain water content was measured to reflect the severity of brain edema. Bars indicate the mean  $\pm$  SD,  $n = 3$ ,  $**p < 0.01$  versus sham group,  $*p < 0.05$  versus sham group,  $#p < 0.05$  versus ASO-NC group,  $t$ -test. (E) TTC-stained brain slices in sham, MCAO, ASO-NC, and ASO-*Neat1* mice at 24 h after MCAO. (F) Comparison of the percentages of infarct volume between each group of mice.  $n = 5$ ,  $**p < 0.01$  versus ASO-NC, Mann-Whitney test. An ELISA examined the protein levels of IL-1 $\beta$  (G), IL-6 (H), TNF- $\alpha$  (I), IL-4 (J), and IL-10 (K) in the infarcted cortex at 24 h after MCAO. Data represent the mean  $\pm$  SD.  $n = 5$ .  $*p < 0.05$ ,  $**p < 0.01$ , and  $***p < 0.001$  versus sham group;  $***p < 0.01$ , and  $####p < 0.001$  versus ASO-NC,  $t$ -test.

a homologous lncRNA for *NEAT1*, suggesting that our study may have translational value.

In the presence of microorganisms, the acute inflammatory response is usually rapid, specific, and self-limiting to avoid inflammation-mediated damage to adjacent tissues.<sup>34</sup> However, in the absence of microorganisms, sterile inflammation occurs in the tissue after ischemic stroke. The triggers of sterile inflammation are the elements of damaged tissues, collectively referred to as

damage-associated molecular patterns that activate local microglia through pattern recognition receptors, including toll-like receptors.<sup>5</sup> The local immune response is amplified, subsequently leading to a massive invasion of systemic immune cells.<sup>35</sup> In our study, the results of immune cell deconvolution estimation showed that the ratio of microglia gradually increased after stroke, while the ratio of monocytes decreased. There are two possibilities for this change. One is intrinsic monocytes are transformed

**Figure 6** *Neat1* knockdown alleviated the ischemic brain tissue damage and suppressed microglia activation after MCAO. (A) Representative images of histological staining of the cortex and striatum from mice after MCAO. Coronal sections were stained with H&E (B) and immunohistochemistry of anti-IBA1 (C). Scale bar, 20  $\mu$ m. The yellow box shows the enlarged area.

into microglia and the other is infiltration of peripheral macrophages to the damaged brain tissue. In either case, this result indicates that microglia play a key role in the inflammatory response. Following ischemic stroke, microglia are activated within 4 h,<sup>36</sup> leading to the production of cytokines and chemokines and leukocyte infiltration. The activated microglia are divided into M1 or M2 activation phenotypes; M1 releases cytotoxic substances, eliciting inflammation and contributing to cell death, while M2 clears cellular debris through phagocytosis and the release of trophic factors.<sup>37</sup> M1 activation has been mostly reported in the early course of the acute proinflammatory response and possesses antigen-presenting capacity.<sup>38</sup> In addition, recent research has shown that *Neat1* knockdown could ameliorate LPS-Induced inflammatory responses by promoting M2 polarization in a mouse macrophage cell line.<sup>39</sup> This is consistent with our ELISA test; the anti-inflammatory factors IL10 and IL4 increased after *Neat1* knockdown. Although we did not perform further experiments to prove whether the specific type of microglia inhibited by ASO-*Neat1* was M1 or M2, according to the level of the proinflammatory factors detected by ELISA, it can be inferred that ASO-*Neat1* is likely to inhibit the activation of M1 microglia and exert anti-inflammatory effects. A very recent study reported *Neat1* is an innate immunity mediator in that translocation from nuclei to the

cytoplasm occurs with inflammatory stimuli and it promotes the activation of NLRP3, NLRC4, and AIM2 inflammasomes.<sup>40</sup> Taken together, due to inflammation being inhibited, brain tissue damage is alleviated, indicating that suppressing the inflammatory response in the acute phase of ischemic stroke is particularly important for saving neurons and decreasing disability and mortality.

A previous study showed that, with activation of microglia through Janus kinase JAK1 signaling, interferon  $\gamma$  activates the STAT1 factor and increases the production of proinflammatory cytokines, such as TNF $\alpha$ , IL-23, IL-1 $\beta$ , IL-12, chemotactic factors, reactive oxygen species, and NO.<sup>41</sup> It has been demonstrated that microglia polarization to M1 also involves NF $\kappa$ B activation.<sup>42</sup> Our KEGG signaling pathway analysis results showed that JAK-STAT and NF $\kappa$ B pathway activation were consistent with these findings.

Nevertheless, this study had limitations. First, the deconvolution analysis of the immune cell proportion could have introduced systematic bias. Future studies with a higher resolution, such as single-cell RNA sequencing (scRNA-seq), should be performed.<sup>43,44</sup> Second, although the upstream of lncRNA is regulated by methylation, histone modification, and gene copy number variation, there is no database for the upstream mechanism leading to differential expression of lncRNA. It is difficult

to predict which molecules upstream of *Neat1* are regulated. Third, we lacked the transcriptome data of brain tissue from human ischemic stroke, so it is impossible to know whether *Neat1* has the same differential expression in ischemic stroke patients and whether it has the same biological function as rodents. Fourth, studies of lncRNA loss-of-function in vivo require more knockdown efficiency than mRNAs, due to their lower abundance. The new approach, such as CRISPR-Cas9 lncRNA knockout, may be more specific and may have fewer side effects.<sup>31,45</sup>

## Conclusions

Our study combined bioinformatics analyses of genome-wide RNA-seq datasets and revealed that *Neat1* is up-regulated in ischemic stroke and promotes activation of microglia in vivo, and knockdown of *Neat1* prevents cerebral ischemic damage caused by acute neuroinflammation. However, although using ASO to knock down *Neat1* had an apparent therapeutic effect, as other molecules that may interact with *Neat1* and further mechanism studies are still required.

## Data Sharing Statement

The data that support the findings of this study are openly available in GEO at <https://www.ncbi.nlm.nih.gov/gds> (GEO accession: GSE112348).

## Acknowledgments

We thank Dr. Jianming Zeng (University of Macau) and all the Bioinformatics team members, biotrainee, for generously sharing their experience of RNA-seq analysis. We also thank Professor Yu Guangchuang for his help in using ‘clusterProfiler’ R package.

## Funding

This work was funded by the Science and Technology Project Foundation of Guangdong province (Grant number: 2016A020215098), the Key Project of Clinical Research of Southern Medical University (Grant number: LC2016ZD024), the National Key Research Development Program (Grant numbers: 2016YFC1300804, 2016YFC1300800), and the Guangdong Provincial Clinical Medical Centre for Neurosurgery (Grant number: 2013B020400005).

## Journal of Inflammation Research

### Publish your work in this journal

The Journal of Inflammation Research is an international, peer-reviewed open-access journal that welcomes laboratory and clinical findings on the molecular basis, cell biology and pharmacology of inflammation including original research, reviews, symposium reports, hypothesis formation and commentaries on: acute/chronic inflammation; mediators of inflammation; cellular processes; molecular

mechanisms; pharmacology and novel anti-inflammatory drugs; clinical conditions involving inflammation. The manuscript management system is completely online and includes a very quick and fair peer-review system. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/journal-of-inflammation-research-journal>
