Background: Presently, no study reported the function of cathepsin H (CTSH) in thyroid carcinoma (THCA). The aim of present study was to initially explore the factors affecting CTSH expression, and association between CTSH expression and survival rate in THCA.

Methods: We explored mRNA expression of CTSH in normal and BRCA tissues, and evaluated prognostic impact of CTSH expression on the overall survival of THCA patients. Then, related factors influencing CTSH mRNA expression in THCA were analyzed. Functional enrichment analysis was performed to reveal the potential function of CTSH involved in THCA. We also constructed PPI network among co-expressed genes of CTSH to determine hub genes, followed by association analysis on hub genes with CTSH.

Results: (1) CTSH mRNA was highly expressed in THCA compared with normal group ($P<0.001$). High expression of CTSH was conducive to the overall survival of THCA patients ($P=0.0027$). CTSH was then determined as an independent prognostic factor in THCA ($P=0.024$). (2) The mRNA expression of CTSH was statistically related to patient's histological type, N stage, T stage, tumor stage and sample type (all $P<0.001$). CTSH copy number variation and methylation also influenced its mRNA expression (all $P<0.001$). (3) Pathway analysis indicated that CTSH mainly participated in cancer-related pathways, such as hedgehog signaling pathway, cytokine-cytokine receptor interaction and JAK-STAT signaling pathway (all $P<0.05$). (4) The top 10 co-expressed genes in whole PPI network showed significant correlation with CTSH expression (all $P<0.001$).

Conclusion: CTSH higher expression was observed in THCA, which caused a good prognosis of patients. CTSH expression might be regulated by multiple factors including clinical characteristic, methylation, copy number and other genes. This study demonstrated the clinical significance of CTSH in THCA, as well as revealed the potential pathway associated with CTSH involved in thyroid cancer.

Keywords: cathepsin H, thyroid carcinoma, high expression, prognosis

Introduction

The incidence of thyroid carcinoma (THCA) was growing the fastest among all malignancies worldwide, particularly in women.^{1,2} Financial pressure commonly appeared in thyroid cancer than other malignancies.³ Largely due to the treatability and favorable survival, THCA has been considered as a “good cancer” which permeated the medical culture.⁴ However, many patients with well-differentiated THCA suffered a persistent and severe decrease in quality of life, lived with fear of recurrences, and commonly experienced feelings of isolation.³ But should not be ignored was that cancer metastasis and proliferation remained as the primary causes of poor prognosis and death in THCA patients.⁵ Thus, there was a compelling need

to explore the mechanisms underlying pathogenesis of THCA, improved the prognosis and life quality of THCA patients.

Cathepsins are lysosomal proteolytic enzymes, which function as cysteine proteinase and play an important role in the catabolism of proteins.⁶ The potent proteolytic activity of cathepsins is known to affect the fate of many intracellular as well as extracellular targets, and deregulation of these functions is associated with tumor proliferation, growth and metastasis.⁷ Extracellular cathepsins were commonly believed to be of central importance in cancer progression by modulating the architecture of the extracellular matrix, intracellular cathepsins have been established as being of extreme significance in mediating cell death through apoptosis.⁸ The therapeutic-targeting potential of cathepsins and their use as reliable prognostic markers has been reported.⁹ Among all the cathepsins, cathepsin H (CTSH) was far less studied and observed in tissues of primary and metastatic tumors in many cancer types. Abnormal expression of CTSH has been found in colorectal carcinoma,¹⁰ breast cancer,¹¹ and prostate cancer,¹² and over expression of CTSH in these cancers was associated with more aggressive disease. Conversely, the patients with head and neck cancer showed a lower level of CTSH than the normal tissue.¹³ Despite the well-known association between CTSH expression and progression in various cancers, the underlying role of CTSH in THCA remained unclear.

The present study was conducted to investigate the expression and prognostic value of CTSH in THCA. We found that CTSH was over-expressed in THCA, and high expression was associated with the favorable overall survival. We also explored the possible mechanisms of CTSH in THCA, and provided the potential therapeutic strategies for the treatment of THCA.

Methods

Impact Analysis of CTSH mRNA Expression on Prognosis of Patients

The mRNA expression of CTSH in normal and THCA patients were firstly analyzed in GSCA database (<http://bioinfo.life.hust.edu.cn/GSCA>). The impact of CTSH expression on overall survival of THCA patients was then evaluated in Kaplan–Meier plotter database (<http://kmplot.com/>). A restrict 10-year survival analysis on CTSH was also performed based on gender and cancer stages. In addition, we took clinical characteristic, immune cell and tumor purity into

consideration, and conducted Cox regression analysis to predict the independent prognostic value of CTSH in THCA.

Association Analysis Between CTSH mRNA Expression and Related Factors

Association between CTSH mRNA expression and clinical data of THCA patients were firstly evaluated in Mexpress database (<https://mexpress.be/>). A total of 13 parameters were enrolled in the association analysis, including gender, age at initial pathologic diagnosis, metastatic site, neoplasm depth, neoplasm length, neoplasm width, pathologic primary tumor (T), pathologic regional lymph nodes (N), pathologic distant metastasis (M), new tumor event after initial treatment, histological type, person lifetime risk radiation exposure indicator, person neoplasm cancer status, tumor stage, sample type and copy number. Subsequently, CTSH mRNA expression was compared in terms of significant parameters with statistical significance. In addition, the effects of CTSH methylation and CNV (Copy Number Variation) on the mRNA expression and overall survival of patients were assessed in GSCA database. Correlation between CTSH mRNA expression and abundance of immune cells was also explored in TISIDB database (<http://cis.hku.hk/TISIDB/>).

CTSH mRNA and Protein Expression in Normal and Cancer Tissues

The Human Protein Atlas (HPA) database (<https://www.proteinatlas.org/>) is a Swedish-based program with the aim to map all the human proteins in cells, tissues and organs using integration of various omics technologies, including antibody-based imaging, mass spectrometry-based proteomics, transcriptomics and systems biology. The mRNA and protein expressions of CTSH in normal and human cancer tissues were first explored through HPA database.

Genetic Alteration of CTSH in THCA

The gene mutation played an important role in the cancer progression. The genetic alteration of CTSH in THCA was explored through Thyroid Carcinoma (TCGA, Firehose Legacy) dataset (n=397) in cBioportal database (<http://www.cbioportal.org/>) to obtain the mutation frequency and sites. The mutation types and nucleotide mutation of CTSH in THCA was subsequently assessed in Catalogue Of Somatic Mutations In Cancer (COSMIC) database (<https://cancer.sanger.ac.uk/cosmic>). COSMIC was the world's

Figure 1 CTSH mRNA expression analysis. **(A)** Differential expression of CTSH mRNA in normal and THCA tissues. Survival time was compared with Kaplan-Meier and logrank test.

largest and most comprehensive resource for exploring the impact of somatic mutations in human cancer.

Enrichment Analysis

For better understanding the role of CTSH in THCA, we got some co-expressed genes playing similar function with CTSH from cBioportal database. The 207 co-expressed genes with $P < 0.001$ and absolute correlation coefficient > 0.6 were selected for the further enrichment analysis. Functional enrichment analyses were performed in Metascape database (<https://metascape.org/>) for GO annotation and WebGestalt (<http://www.webgestalt.org/>) database for KEGG pathway exploration. Additionally, GSEA analysis was performed to explore significant pathways associated with CTSH involved in THCA. The terms with nominal P -value < 0.05 and FDR $< 25\%$ were considered as significant events.

We also constructed protein-protein interaction (PPI) network of 207 co-expressed genes through String database (<https://string-db.org/>), and visualized the PPI network by Cytoscape. Among the whole PPI network, we determined the top 10 hub genes using MCC gene ranking methods. Expression correlation between CTSH and 10 hub genes was then evaluated involved in THCA by adjusting the patient's age.

Statistical Analysis

Related statistical analyses were performed with SPSS 22.0. Independent *t*-test was used for comparisons between two groups, and comparisons between more than three groups were conducted using ANOVA with a post hoc multiple comparison. Survival outcomes including overall survival was compared by Kaplan-Meier analysis and

logrank test. Spearman correlation analysis was used to present relationship between 2 variables. P value less than 0.05 was considered as statistically significant.

Results

Impact of CTSH mRNA Expression on the Prognosis of THCA Patients

Differential expression analysis showed that expression of CTSH mRNA in THCA was higher than that in normal group (Figure 1A), and difference presented statistical significance ($P < 0.001$). Survival analysis indicated that CTSH mRNA high expression prolonged the overall survival time of THCA patients (Figure 1B) and caused a favorable prognosis (HR=0.24, $P=0.0027$).

Restrict analysis on the patient's survival (Table 1) indicated that the survival difference between high and low expression groups was statistically significant both in female ($P=0.0300$) and male ($P=0.0008$) patients. The survival difference between two groups was also observed in patients with stage 1 ($P=0.0051$) and stage 3 ($P=0.0078$). Taking the clinical characteristics and immune cells into consideration,

Table 1 Restrict Survival Analysis in THCA Patients

Subtypes		HR (95% CI)	Log Rank P
Gender	Female (n=367)	0.27 (0.08–0.96)	0.0300
	Male (n=135)	0.09 (0.02–0.51)	0.0008
Cancer stages	I (n=281)	0 (0-Inf)	0.0051
	II (n=52)	0 (0-Inf)	0.0720
	III (n=112)	0 (0-Inf)	0.0078
	IV (n=55)	0 (0-Inf)	0.2200

Note: The survival time was compared with Kaplan-Meier and log rank test.

we performed multivariate cox regression analysis to predict the independent prognostic factors of THCA. The results (Table 2) indicated that parameters of age, stage 4, purity, CD4 T cell, macrophage and CTSH were independent factors for THCA prognosis. It followed that CTSH expression was associated with survival of THCA patients as well as determined as an independent prognostic factor, suggesting the clinical significance of CTSH in THCA.

Association Between CTSH mRNA Expression and Related Factors

Due to the significance of CTSH mRNA expression on the survival of THCA patients, we then explored the related

clinical characteristics of THCA patients affecting CTSH mRNA expression level (Figure 2). Among 13 phenotypes, we found that CTSH mRNA expression was statistically related to 6 parameters, including histological type, pathologic-N, pathologic-T, tumor stage, sample type and copy number (all $P < 0.001$). Remaining parameters showed no statistical correlation with CTSH mRNA expression.

We subsequently explored the detailed expression of CTSH mRNA expression based on the above significant phenotypes. The expression comparison analysis (Figure 3) indicated that expression of CTSH mRNA was relatively lower in sample type of solid tissue normal (all $P < 0.001$). For histological type, classical patients showed higher CTSH mRNA expression (all $P < 0.05$). Higher expression of CTSH mRNA expression was also observed in T3 and N1 stage (all $P < 0.05$). In terms of tumor stage, patients in stage III presented lower expression of CTSH mRNA expression (all $P < 0.01$).

In addition, we evaluated the impacts of CTSH methylation and copy number variation (CNV) on its mRNA expression level. The analysis showed that CTSH mRNA expression was negatively related to methylation level (Figure 4A, $P < 0.001$), but positively correlated with CTSH CNV (Figure 4B, $P < 0.001$). Further, we found that CTSH methylation level in THCA was lower than that in normal patients (Figure 4C, $P < 0.001$). An integral survival analysis showed no correlation between methylation status and survival time (Figure 4D). But when we only controlled age and gender, a correlation between

Samples are arranged from left to right. The samples are ordered by the expression of CTSH. So in this case, samples with low CTSH expression are located on the left side of the plot, whereas samples with high CTSH expression are on the right. * $P < 0.05$, ** $P < 0.01$ and *** $P < 0.001$.

Figure 3 Association between CTSH mRNA expression and significant clinical features in THCA. The data was presented as median and 95% CI (black line). * $P<0.05$ and ** $P<0.01$ and *** $P<0.001$. The one-way ANOVA was used to compare differences among groups, followed by post hoc multiple comparison.

Abbreviation: CI, confidence interval; T, primary tumor; T1, small, minimally invasive within primary organ site; T2, larger, more invasive within the primary organ site; T3, larger and/or invasive beyond margins of primary organ site; T4, very large and/or very invasive, spread to adjacent organs. N, regional lymph nodes; N0, no regional lymph node metastasis; N1, metastases in 1 to 3 axillary lymph nodes.

methylation status and prognosis was observed (Figure 4E). The T, N, M and cancer stage did not influence the survival difference between 2 groups with different methylation levels. The CNV of CTSH did not directly influence the overall survival of THCA patients (Figure 4F).

From Cox regression analysis, we found the significance of immune cell on the patient's survival. We then evaluated the correlation between CTSH mRNA expression and abundance of B cell, CD4 T cell and macrophage. Among B cells, Mem_B cell showed the highest correlation with CTSH mRNA expression. Regarding CD4 T cell, Tcm_CD4 presented the strongest relation with CTSH mRNA expression. The correlation analysis between CTSH mRNA expression and Mem_B cell, Tcm_CD4 cell and macrophage abundance was presented in Figure 5.

The Expression of CTSH in Normal and Cancer Tissues

Through HPA database analysis, we found that mRNA expression of CTSH has characteristic of tissue specificity, and CTSH expression was obviously enhanced in the tissue of lung (Figure 6A). In addition, mRNA expression was also enriched in lymphoid tissues such as lymphoid node and tonsil. The CTSH protein expression exerted no tissue specificity (Figure 6B).

Besides the expression overview in normal tissue, the abnormal expression of CTSH in cancer tissues was also assessed. The above RNA expression overview indicated the low cancer specificity of CTSH (Figure 7A), and

relatively higher expression was observed in thyroid cancer, lung cancer and urothelial cancer. The protein expression overview (Figure 7B) suggested that higher expression appeared in prostate cancer, thyroid cancer and renal cancer. Among human cancers, both mRNA and protein expressions of CTSH in thyroid cancer was relatively higher than that in other cancer types.

The Genetic Alteration of CTSH in THCA

The cBioPortal database contained 397 samples with THCA, and 3% of patients presented the genetic alteration of CTSH. The mutation site was located at protein domain I233Nfs*3 (Figure 8A). The mRNA high expression showed the highest alteration frequency in both papillary and follicular thyroid cancer (Figure 8B). The main mutation type of CTSH in thyroid carcinoma was missense substitution (75.00%) (Figure 8C). The nucleotide mutation was mainly presented as G>T (50.00%) (Figure 8D).

Enrichment Analysis

In order to obtain a more in-depth understanding of the CTSH in THCA, we determined 206 co-expressed genes playing similar function with CTSH as setting the threshold of $P<0.001$ and absolute Spearman correlation >0.6 . GO annotation was then performed. The GO terms after clustering were significantly enriched in 20 terms (Figure 9A), such as actin cytoskeleton organization, regulation of hormone levels, positive regulation of transferase activity and regulation of membrane potential. To

systematically clarify the key pathways involved in THCA pathogenesis, pathway enrichment analysis was subsequently carried out. KEGG pathway enrichment analysis showed that these co-expressed genes were significantly enriched in hedgehog signaling pathway, thyroid hormone synthesis, adherens junction and apelin signaling pathway (Figure 9B).

Next, GSEA analysis on CTSH involved in THCA was performed to explore significant pathways. A total of 43

significant pathways were detected containing 28 positive correlated and 15 negative correlated pathways with CTSH. Because of favorable impacts of CTSH high expression on the survival of patients, we just focused on positive related pathways of CTSH. The analysis in Figure 10 showed that CTSH positively correlated with pathways of natural killer mediated cytotoxicity, cytokine–cytokine receptor interaction and JAK-STAT signaling pathway. In addition, we found that hedgehog signaling

pathway was upregulated in CTSH low expression group, indicating a negative correlation between CTSH and hedgehog pathway.

PPI Network Analysis

The String online database was employed to construct the PPI network of co-expressed genes, then, the Cytoscape software was used to visualize interactions network. After analysis, there were 120 nodes and 134 edges in PPI network, and the most significant networks were presented in Figure 11A. From the PPI network, the top 10 nodes ranked by MCC method were determined (Figure 11B). The top 10 genes and corresponding score were as follows: TIMP1 (35), PRKACB (27), MFGE8 (27), SERPINA1 (27), ADCY8 (26), GNAI1 (24), FAM20C (24), MXRA8 (24), ANXA1 (18) and ITPR1 (16). Finally, we explored the correlation between CTSH and 10 hub genes involved in THCA by adjusting the patient's age. Association analysis (Figure 12) showed that expression of 7 hub genes was positively related to CTSH expression, while 3 hub genes negatively correlated with CTSH expression.

Discussion

Cathepsins have recently emerged as enzymes that were active in cancer development. However, there was no

report on the role of cathepsin H (CTSH) in THCA. In the present study, we initially evaluated the expression of CTSH in THCA patients. Our results showed that CTSH was highly expressed in THCA patients compared with the normal group. CTSH expression correlated with the cancer type, N stage and clinical stage of THCA patients. In addition, CTSH expression was positively associated with the prognosis of patients with THCA, and high expression of CTSH improved the prognosis in terms of overall survival. Several researches have reported the favorable role of CTSH in human cancers. The study suggested that high expression of CTSH correlated with a better outcome and increased the survival time of patients with head and neck carcinoma.¹⁴ The low expression of CTSH was not conducive to the prognosis and led to a highest risk of death in patients with colorectal cancer.¹⁵ Inversely, other investigations showed the undesirable effects of CTSH in cancers. Previous study showed the significant difference of CTSH level between lung tumor and non-tumorous tissues.¹⁶ This study further indicated that the difference was associated with the cigarette smoking status, and smokers with high level of CTSH experienced poor survival. In addition, the expression of CTSH significantly increased in melanoma patients as well, and metastatic melanoma patients with high contents of CTSH experienced shorter overall

Vertical axis showed the enrichment score. Peak value of line chart indicated the enrichment score of gene set. The genes in front of peak value were regarded as the core genes in this gene set. The peak value was located at red section, which indicated that the genes set was positively associated with one gene expression. While located in blue section, it indicated genes set was negatively associated with one gene expression.

survival rates.¹⁷ All these findings revealed that CTSH could be identified as a significant prognostic factor for patients with cancers.

CTSH has been considered to play a vital role in tumor progression. CTSH-mediated processing of talin might

promote cancer cell progression by affecting integrin activation and adhesion strength.¹⁸ CTSH could indirectly regulate the bone morphogenetic protein-4 (BMP-4) in various human cell lines.¹⁹ Moreover, up-regulation of CTSH not only promoted the invasion of tumor cells by

degradation of the extracellular matrix,²⁰ also increased the cell migration by activation of the extracellular signal-regulated kinase.²¹ Another study demonstrated the important tumor-promoting roles for CTSH using mouse model of human cancer,²² which indicated that deletion of CTSH significantly impaired the angiogenic switching and resulted in a reduction in the subsequent number of tumors that formed. It followed that CTSH participated in the human cancers through various processes.

In this study, we also performed the enrichment analysis to reveal the potential role of CTSH involved in THCA. Our results indicated that CTSH was significantly associated with the apelin and hedgehog signaling pathway. Unfortunately, no studies reported the correlation between CTSH expression and these two pathways up to now. A recent study showed that apelin inhibition could prevent resistance and metastasis associated with anti-angiogenic therapy.^{23,24} Apelin was associated with the

promotion of hepatocellular carcinoma through activating PI3K/Akt pathway and was a druggable target.²⁵ In addition, apelin can induce the lymphangiogenesis and, accordingly, play an important role in lymphatic tumor progression.²⁶ This study opened the door for the development of novel anticancer therapies targeting lymphangiogenesis. In addition, Apelin has known pleiotropic effects on the immune microenvironment. The Apelin expression can be promoted by Tregs.²⁷ When Apelin induction was combined with an anticancer vaccine that boosts the immune system and generates natural killer T (NKT) cells, the normalized vessels allowed trafficking of NKT cells to the tumor and induced a strong antitumor response.²⁸ Hedgehog pathway has been demonstrated to closely correlate with the progression of human cancers. Previous study indicated that hedgehog signaling pathway participated in the EMT and invasion of non-small cell lung carcinoma.²⁹ The blockage of hedgehog signaling

Figure 12 Correlation analysis between CTSH and 10 hub genes expression in THCA which was adjusted by patient's age. Horizontal axis indicated mRNA expression of hub genes, and vertical axis referred to CTSH mRNA expression. Spearman correlation analysis was used to present relationship between 2 variables.

promoted the autophagic apoptosis in nasopharyngeal carcinoma.³⁰ Moreover, the inhibition of hedgehog signaling pathway induced the apoptosis and impeded the proliferation, migration, and invasion in epithelial ovarian cancer.³¹ In terms of immune system, hedgehog pathway inhibition can alter fibroblast composition and immune infiltration in cancer microenvironment.³² Hanna et al identified that hedgehog signaling mediated a molecular crosstalk between cancer cells and macrophages, which culminated in alternative polarization of macrophages.³³ It followed that Apelin and hedgehog signaling pathways were of great significance in the progression of human cancers.

We finally determined the important hub genes among these co-expressed genes with CTSH. The study indicated that regulation of TIMP1 may be involved in tumor invasion and metastasis in oral cancer,³⁴ papillary thyroid cancer³⁵ and colon cancer.³⁶ MFGE8 could reduce the apoptosis and promote proliferation,³⁷ also regulate the pathologic angiogenesis.³⁸ ITPR1 was able to induce the autophagy.³⁹ GNAI1 can suppress the tumor cell migration and invasion.⁴⁰ It followed that CTSH and these co-expressed genes played a significant role in cancer and were implicated in tumorigenic processes, such as angiogenesis, proliferation, apoptosis and invasion. Although several targets associated with CTSH in THCA were detected, the detailed regulation and interaction between CTSH and hub genes remain unclear,

which needs further confirmation through experimental verification.

Conclusion

This study initially revealed the clinical significance of CTSH in THCA. High expression of CTSH was found in THCA, which was positively associated with overall survival of patients. CTSH was further determined as an independent prognostic factor in THCA. Several factors exerted potential regulation effects on CTSH mRNA expression including clinical characteristics, copy number, methylation level and other genes. We initially found CTSH might correlate with hedgehog signaling pathway and JAK-STAT signaling pathway, and detailed regulation should be further verified by series of functional analyses. The present work provided a new molecular biomarker for THCA treatment. However, further studies are still needed to explore the specific molecular mechanisms of CTSH for THCA initiation and progression in the future.

International Journal of General Medicine

Dovepress

Publish your work in this journal

The International Journal of General Medicine is an international, peer-reviewed open-access journal that focuses on general and internal medicine, pathogenesis, epidemiology, diagnosis, monitoring and treatment protocols. The journal is characterized by the rapid reporting of reviews, original research and clinical studies

across all disease areas. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/international-journal-of-general-medicine-journal>
