Purpose: The study investigated the molecular mechanisms that killed pancreatic cancer cells, including cancer stem cells (CSCs), by carbon ion beam irradiation alone or in combination with miRNA-200c under in vitro and in vivo conditions.

Methods: Human pancreatic cancer (PC) cells, PANC1 and PK45, were treated with carbon-ion beam irradiation alone or in combination with microRNA-200c (miR-200c) mimic. Cell viability assay, colony and spheroid formation assay, quantitative real-time PCR analysis of apoptosis-, autophagy-, and angiogenesis-related gene expression, xenograft tumor control and histopathological analyses were performed.

Results: The cell viability assay showed that transfection of the miRNA-200c (10 nM) mimic into pancreatic CSC (CD44+/ESA+) and non-CSC (CD44-/ESA-) significantly suppressed proliferation of both types of cell populations described above. Combining carbon-ion beam irradiation with the miRNA-200c mimic significantly reduced the colony as well as spheroid formation abilities compared to that observed with the treatment of carbon-ion beam alone or X-ray irradiation combined with the miRNA-200c mimic. Moreover, the combination of carbon ion beam irradiation and miRNA-200c mimic increased the expression of apoptosis-related gene BAX, autophagy-related genes *Beclin-1* and *p62*, addition of gemcitabine (GEM) further enhanced the expression of these genes. In vivo data showed that carbon-ion beam irradiation in combination with the miRNA-200c mimic effectively suppressed xenograft tumor growth and significantly induced tumor necrosis and cavitation.

Conclusion: The combination of miRNA-200c mimic and carbon ion beam irradiation may be powerful radiotherapy that significantly kills pancreatic cancer cells containing CSCs and enhances the effect of carbon-ion beam irradiation compared to carbon-ion beam irradiation alone.

Keywords: pancreatic cancer stem cell, miR-200c, carbon-ion beam

Introduction

Pancreatic cancer (PC) is one of the most aggressive cancers. It is difficult to improve its prognosis, especially for locally advanced pancreatic cancer (LAPC) despite remarkable medical improvement.¹⁻³ Surgical resection is one of the major treatments for LAPC, but most patients experience recurrence and metastasis, resulting in a 5-year survival rate of less than 20%.^{4,5} Recent reports indicate that stereotactic body radiotherapy (SBRT), intensity modulated radiation therapy (IMRT), or proton beam radiation therapy alone or in combination with

chemotherapy resulted in relatively good outcome. However, for the nonresectable cases, the 2-year survival rate is around 20–30%.^{6–14}

Over the past 25 years, more than 600 patients with LAPC have been treated with carbon-ion radiotherapy (CIRT) at the National Institute of Radiological Sciences (NIRS) and patients treated with CIRT along with gemcitabine (GEM) achieved promising outcomes. However, the 2-year overall survival rate was only around 50%.^{15–18} We have previously reported that carbon-ion beams combined with GEM predominantly destroyed pancreatic cancer stem cells (CSCs).¹⁹ On the other hand, accumulating evidence indicates that microRNAs (miRs) play a pivotal role in cancer and function as tumor suppressors and oncogenes.^{20–24} In another recent report, we demonstrated that carbon-ion beam irradiation combined with miR-34 mimic and/or rapamycin or miR-29b effectively eradicated high-grade chondrosarcoma CSCs and osteosarcoma cells via the mTOR-FOXO3 axis and the PTEN/AKT-SPI1 pathway.^{25,26} miR-200c, known as a tumor suppressor, is involved in inhibiting tumor growth and metastasis by suppressing the CSCs, this process is thought to be closely related to drug resistance and recurrence.^{27–35} Thus, it is very important to develop a strategy to eliminate CSCs efficiently.^{36–39} Recent reports indicate that miR-200c enhances radiosensitivity in several cancer types such as breast, lung, head and neck cancers.^{40–52} Our recent findings demonstrated that high linear energy transfer (LET) carbon-ion beam irradiation alone or in combination with chemotherapy or molecular targeted agents effectively enhanced the CSC-killing effects in several cancer cell types.^{52–57} Therefore, we hypothesized that the addition of the miRNA-200c mimic may enhance the carbon-ion beam radiosensitivity.

Thus, we explored the molecular mechanism of killing the pancreatic cancer cells, including CSC, by carbon-ion beam irradiation alone or in combination with miRNA-200c under in vitro and in vivo conditions.

Materials and Methods

Cell Culture

PANC1 and PK45 cells were obtained from the American Type Culture Collection. The unsorted cells were cultured in Dulbecco's Modified Eagle medium (DMEM) with 10% heat-inactivated fetal bovine serum (Biological Industries, Beit-Haemek, Israel), and 100

units/mL penicillin, 100 µg/mL streptomycin (Invitrogen) supplemented with 5% CO₂ at 37°C. The medium was changed every 3 days. CSCs and non-CSCs isolated from PANC1 and PK45 cells were cultured in the PromoCell Cancer Stem Cell *medium* (PromoCell, Heidelberg, Germany).

Reagents

The antibodies used in the present study were as follows: mouse anti-human CD44-PE (BD, Biosciences, USA), mouse anti-human CD326-FITC (EpCAM/ESA, Miltenyi Biotec, Germany), and gemcitabine (GEM). Gemcitabine (Gemzar) was purchased from Eli Lilly Japan K.K., Kobe, Japan. A stock solution of gemcitabine (1 mM in PBS) was diluted to appropriate concentrations just before use.

Irradiation

Cells were treated with a 290 MeV/neutron carbon-ion beam with a 6-cm spread-out Bragg peak (SOBP), which was produced by the heavy ion medical accelerator in Chiba (HIMAC) at the National Institutes for Quantum and Radiological Science and Technology (QST) in Japan.³⁰ As a reference, cells were exposed to conventional 200 kVp X-ray irradiation (TITAN-320, GE Co., USA). Cells were irradiated with 2, 4, or 6 Gy of X-rays or carbon-ion beams at 1, 2, or 3 Gy.

Transient Transfection of the miR-200c Mimic

miR-200c mimic and the control were purchased from Bioneer Corporation (Daejeon, South Korea). Cells were transfected with 10 nM control or the miR-200c mimic using the miRNA Transfection Reagent Lipofectamine 2000 (Invitrogen, Carlsbad, CA) according to the manufacturer's instructions.

Colony Formation and Spheroid Formation Assays

Cells were treated with the *miR-200c* mimic for 24 h and then incubated for 7–9 days. The colonies were then fixed with methanol, stained with 0.2% methylene blue (Sigma-Aldrich, St. Louis, MO), and counted. A spheroid formation assay of the CD44+/ESA+ and CD44-/ESA- cell populations sorted from the PANC1 and PK45 cells was performed as described previously.²⁰ Briefly, 3000 cells per well were plated in low cell adhesion 96-well plates

(SUMILON, Sumitomo Bakelite, Tokyo, Japan) for 1 week and the sphere area size was estimated. Data are displayed as average size after 1 week of incubation using the WinROOF 5.6 software (Mitani Corporation, Tokyo, Japan).

Cell Viability Assay

The CellTiter-Glo Luminescent Cell Viability Assay (Promega), a method that determines the number of viable cells in the culture based on the quantification of ATP present, was used to estimate the cell viability. In the homogeneous assay, a single reagent (CellTiter-Glo[®] Reagent) was added directly to the cells grown in the serum-supplemented medium. Cell viability was also tested by the Trypan Blue exclusion test, in which dead or dying cells were stained, based on the principle that living cells exclude trypan blue dye and do not stain.

Real-Time RT PCR Analysis for the Expression of Various Genes Related to Apoptosis and Autophagy

RNA was extracted using the Qiagen RNeasy kit, and cDNA was prepared using the RT² First-Strand Kit (SABiosciences, Frederick, Maryland, USA). The expression of apoptosis, autophagy-related genes was analyzed using the LightCycler[®] 96 real-time PCR system (Roche, Basel, Switzerland). For data analysis, the $\Delta\Delta C_t$ method was applied using the RT PCR software package and statistical analysis was performed as described previously.^{26,27} The primer sequences used in this study are shown in Table 1. GAPDH was used as a housekeeping gene.

In vivo Xenograft Tumor Control Assay After Carbon-Ion Beam Irradiation Alone or in Combination with miR-200c Mimic

PK45 cells were injected into the right leg of NOD-SCID mice. A total 28 NOD-SCID male mice (6–8 weeks) were used in this study. When the xenograft tumor size reached an approximate size of 10 mm, the mice were treated with a carbon-ion beam alone or in combination with miR-200c mimic. The miR-200c mimic was delivered directly to the tumor twice a week for 2 weeks with an in vivo-jet PEI

reagent after carbon ion beam irradiation according to the protocol (Polyplus-Transfection, Strasbourg, France). Briefly, a total 10 μ g of miR-200c mimic was diluted in 10% glucose in ddH₂O in one microtube, and in the other microtube, 1.2 μ L in vivo-jetPEI-Gal (N/P = 6) was diluted in 10% glucose in ddH₂O. Then, the tubes were mixed and incubated for 15 min at room temperature (RT). Finally, the solutions containing miR-200c mimic were injected intratumorally. For histopathological analysis, hematoxylin and eosin (HE) staining were performed using formalin-fixed tumor tissue. All animal experiments were conducted in accordance with QST-NIRS institutional animal welfare guidelines and approved by Animal Experiment Ethics Committee (approval number:17-2008-2, QST).

Statistical Analysis

One-way analysis of variance (one-way ANOVA) and Bonferroni multiple comparison tests were used to the mean differences between the groups using the

Figure 2 (A) Morphological changes of CSCs and non-CSCs delivered from PK45 cells 72 h after treatment with carbon-ion beam irradiation alone, X-ray irradiation alone or in combination with the miR-200c mimic. **(B)** Colony formation of CSCs and non-CSCs delivered from PK45 cells after treatment with carbon-ion beam, X-ray irradiation alone or in combination with the miR-200c mimic. * $p < 0.01$ compared to the control.

and incubated for 2 weeks after transfection with miR-200c. **Figure 2A** shows morphological changes in the CSCs and non-CSCs 72 h after exposure to a carbon-ion beam irradiation (C-1 Gy) alone, X-ray (2 Gy) alone, or the miR-200c mimic (10 nM) alone, or a combination of any of these three treatments. The results showed that the cells were killed by the combination treatment, especially constituting the carbon-ion beam irradiation and miR-200c mimic. As shown in **Figure 2B**, the colony formation ability of the pancreatic CSCs was decreased after treatment with the carbon-ion beam alone, and the miR-200c mimic alone

treatment, and it was significantly further decreased by its combination treatment compared to that with X-ray irradiation alone.

Effects of Carbon-Ion Beam Irradiation Alone or in Combination with miR-200c Mimic on Spheroid Formation Ability of the Pancreatic CSCs

To investigate the spheroid formation ability of the pancreatic CSCs and non-CSCs irradiated with carbon-ion beam alone or in combination with the miR-200c mimic,

PK45

Figure 3 Spheroid formation of CSCs and non-CSCs delivered from PANC1 and PK45 cells after treatment with carbon-ion beam irradiation alone or in combination with the miR-200c mimic. # $p < 0.05$, * $p < 0.01$ compared to the control.

miR200c transfected CSCs and non-CSCs were placed in 96-well round-bottomed Sumilon Celltight spheroid plates (Sumilon, Sumitomo Bakelite Co., Tokyo) and incubated for 7 days. As shown in Figure 3, the spheroid formation ability of the pancreatic CSCs was slightly inhibited after treatment with either carbon-ion beam alone or miR-200c mimic alone. However, this ability showed a further significant reduction when a combination was applied compared to that with X-ray irradiation alone (Figure 3).

Carbon-Ion Beam Irradiation Combined with the miR-200c Mimic Decreases Pancreatic CSC Viability

A CellTiter-Glo luminescent cell viability assay was performed to examine the effects of the combination of miR-200c mimic and the carbon-ion beam irradiation on suppression of pancreatic CSCs and non-CSCs viability. As shown in

Figure 4, the treatment with miR-200c mimic alone significantly inhibited the viability of the pancreatic CSCs, whereas the viability was only slightly inhibited upon treatment with carbon-ion beam irradiation. However, the viability of the pancreatic CSCs was greatly inhibited by the combination treatment of carbon-ion beam irradiation and miR-200c mimic. The same response was observed in non-CSCs.

Effects of Carbon-Ion Beam Irradiation Alone or in Combination with miR-200c Mimic on Expression Genes Related to Apoptosis and Autophagy in Pancreatic CSCs

Quantitative real-time PCR (qPCR) was performed to investigate whether carbon-ion beam irradiation alone or in combination with miR-200c mimic and/or GEM on the effects of the expression of apoptosis-related genes. As

PK45

Viability 72h

Figure 4 Cell viability of non-CSCs and CSCs delivered from PK45 cells after treatment with carbon-ion beam irradiation alone or in combination with the miR-200c mimic. *p < 0.01 compared to the control.

shown in Figure 5A, expression of the apoptosis-related gene *Bax* was increased after exposure to carbon-ion beam irradiation alone but not in the presence of the miR-200c mimic. This *Bax* expression was significantly increased after treatment with carbon-ion beam irradiation combined with miR-200c mimic, and enormously enhanced by the additional treatment of plus GEM in the pancreatic CSCs. The expression of the anti-apoptotic gene *Bcl2* was also increased by carbon-ion beam irradiation alone, and their combination treatment. However, no significant changes were observed by the additional treatment of GEM in the pancreatic CSCs. In conclusion, *Bax* gene expression was increased only by carbon-ion beam irradiation in combination with miR-200c mimic, and the *Bcl2* gene expression was increased by the triple combination treatment of carbon-ion beam irradiation, miR-200c mimic and GEM in the pancreatic non-CSCs.

The expression of autophagy-related genes, *Beclin-1* and *p62*, was increased after carbon-ion beam irradiation alone. A further significant increase was caused by triple combination treatment of carbon-ion beam irradiation, miR-200c mimic and GEM in the pancreatic CSCs. In contrast, *Beclin-1* expression was increased by treatment with carbon-ion beam irradiation alone, or in combination with miR-200c mimic or triple combination of plus GEM. However, the *p62* expression was increased by all treatment combinations in the pancreatic non-CSCs (Figure 5B).

Effects of Carbon-Ion Beam Irradiation Alone or in Combination with miR-200c Mimic on Expression of Angiogenesis-Related Genes in Pancreatic Cancer Stem Cells

To investigate the expression of exposure to carbon-ion beam irradiation alone or in combination with miR-200c mimic and/or GEM on expression of angiogenesis-related genes, the expression of the *HIF1a* and *VEGF* was determined by qPCR. As seen from Figure 5C, the *HIF1a* expression was significantly inhibited by carbon-ion beam irradiation combined with miR-200c mimic compared to miR-200c mimic treatment alone or miR-200c mimic combined with GEM treatment in pancreatic CSCs. The *VEGF* expression increased after exposure to carbon-ion beam irradiation alone, miR-200c mimic and GEM alone or its combination treatment in pancreatic CSCs.

Effects of Carbon-Ion Beam Irradiation Alone or in Combination with miR-200c Mimic on Morphological and Histopathological Changes in Pancreatic Xenograft Tumors

To examine the effect of carbon-ion beam irradiation treatment alone or in combination with miR-200c

Figure 5 (A) Changes in the expression of apoptosis-related genes 96 h after treatment with carbon-ion beam irradiation alone or in combination with the miR-200c mimic and/or gemcitabine in CSCs and non-CSCs delivered from PK45 cells. (B) Changes in the expression of autophagy-related genes 96 h after treatment with carbon-ion beam irradiation alone or in combination with the miR-200c mimic and/or gemcitabine in CSCs and non-CSCs delivered from PK45 cells. (C) Expression changes of angiogenesis-related genes 96 h after treatment with carbon-ion beam irradiation alone or in combination with the miR-200c mimic and/or gemcitabine in CSCs and non-CSCs delivered from PK45 cells. * $p < 0.01$ compared to the control.

mimic on the xenograft tumor growth and associated histopathological changes, we injected PK45 cells into NOD-SCID mice and then treated the tumors after they had grown to a certain size (7–8 mm diameter). As shown in Figure 6A and B, treatment with 15 Gy of carbon-ion beam irradiation in combination with the miR-200c mimic predominantly suppressed the tumor growth compared to that obtained by treatment with miR-200c alone and 30 Gy of carbon-ion beam irradiation alone 1 month after treatment. Two months after treatment, the tumor growth was still regressed by 15 Gy of carbon-ion beam irradiation in combination with the miR-200c mimic. Interestingly, the tumor growth was further regressed by 30 Gy of carbon ion beam irradiation alone, but the tumors were regrown in the miR200c mimic-alone treatment group. Histopathological analysis showed that combined treatment with carbon-ion beam and the miR-200c mimic effectively destroyed the

pancreatic xenograft tumor cells with significant tumor cell necrosis, cavitation and fibrosis compared to the miR-200c mimic-alone treatment. High-dose carbon ion beam irradiation appears to induce more severe tumor cell cavitation (Figure 6C).

Discussion

We found that the viability as well as colony and spheroid formation abilities of the pancreatic CSCs decreased after treatment with carbon-ion beam alone, and miR-200c mimic alone. These abilities were significantly decreased by the combination treatment, whereas X-ray irradiation alone could cause only slight inhibition. This finding indicated that the miR-200c mimic effectively enhanced the carbon-ion radiosensitivity in the pancreatic CSCs. This is partially in line with previous reports that miR-200c increased the radiosensitivity in human cancer cells by

Figure 6 (A) Morphological changes of PK45 xenograft tumor after 30 Gy of carbon ion beam irradiation alone, miR-200c mimic alone or 15 Gy of carbon ion beam irradiation in combination with the miR-200c mimic. (B) Regression of PK45 xenograft tumor before and after treatment with 30 Gy of carbon ion beam irradiation alone, miR-200c mimic alone or 15 Gy of carbon ion beam irradiation in combination with the miR-200c mimic. # $p < 0.05$, * $p < 0.01$ compared to the Control. (C) Histopathological changes in the PK45 xenograft tumor after 30 Gy of carbon ion beam irradiation alone, miR-200c mimic alone or 15 Gy of carbon ion beam irradiation in combination with the miR-200c mimic.

downregulating p-EGFR and p-AKT and inducing apoptosis and autophagy.^{41–44}

It has been reported that miR-200c expression is down-regulated in breast CSCs, and the miR-200c mimic effectively increases breast cancer cell chemosensitivity and inhibits stemness and xenograft tumor growth.^{27–35} Pancreatic cancer patients with a higher expression of miR-200c showed a close correlation with low invasion ability and better prognosis.⁴⁸ The miR-200c mimic decreased pancreatic CSC colony formation, invasion and chemoresistance.^{29,49} In this study, apoptosis-related Bax expression was increased after exposure to carbon-ion beam irradiation alone but not by the miR-200c mimic alone. However, Bax expression was significantly increased after the carbon-ion beam irradiation was combined with miR-200c mimic, and enormously enhanced by triple combination treatment with GEM in the pancreatic CSCs. In comparison, the expression of the anti-apoptotic gene Bcl2 was also increased by the exposure to carbon-ion beam irradiation alone, miR-200c mimic alone or its

combination treatment. However, it was not significantly changed by the triple combination treatment of these agents in the pancreatic CSCs. These data suggest that the Bax gene expression was increased only by carbon-ion beam irradiation in combination with miR-200c mimic. However, Bcl2 gene expression was increased by the triple combination treatment of carbon-ion beam irradiation, miR-200c mimic and GEM in pancreatic non-CSCs. This is partially consistent with previous reports that miR-200c mimic increased the caspase-3 and Bax expression and decreased the Bcl2 expression in human glioblastoma and gastric cancer cells.^{39,50,51}

In this study, expression of autophagy-related genes, *Beclin-1* and *p62*, was increased after carbon-ion beam irradiation alone, a further significant increase was obtained by the additional treatment of GEM in the pancreatic CSCs. A previous report showed that miR-200c inhibited radiation-induced autophagy-related proteins such as LC3AB and p62 in breast cancer cells.⁴⁴ In contrast, Beclin-1 expression was increased by exposure to

carbon-ion beam irradiation alone, or in combination with miR-200c mimic or the triple combination with GEM. However, p62 expression was increased by all treatment combinations in pancreatic non-CSCs. miR-200c has the potential to suppress HIF-1 α /VEGF expression in bladder cancer cells and inhibit angiogenesis, and these regulations were achieved by targeting Akt2/mTOR.²² The investigation on the expression of angiogenesis-related genes, HIF1 α and VEGF showed that HIF1 α expression was significantly inhibited by carbon-ion beam irradiation combined with miR-200c mimic, but not by its isolated treatment in the pancreatic CSCs. VEGF expression was increased by the treatment with carbon-ion beam irradiation alone, miR-200c mimic and GEM alone or its combination treatment in pancreatic CSCs. This finding is partially consistent with a previous report that the miR-200c mimic inhibits the expression of HIF1 α , MMP2, VEGF and E-cadherin in human glioblastoma cells.^{44,45}

Currently, several therapeutic miRNA delivery systems,^{58,59} such as virus-based delivery,⁶⁰ non-viral delivery (artificial lipid-based vesicles,^{45,61–64} polymer-based⁶⁵ or chemical structures,⁶⁶ and extracellular vesicle-based delivery systems^{67,68} have been reported. Reid et al reported that delivery of miR-16 using EDVTM nanocell platform effectively suppressed xenograft malignant pleural mesothelioma in vivo.⁶¹ Coetzee et al reported that therapeutic delivery of miR-200c mimics using liposomal nanoparticle effectively enhanced radiosensitivity in xenograft lung tumor in vivo,⁴³ implying that those of delivery systems may be useful in clinical trial in the future.

In the present study, relatively a low dose of carbon-ion beam irradiation (15 Gy) combined with miR-200c mimic or with high dose of carbon-ion beam irradiation (30 Gy) alone greatly suppressed tumor growth compared to that with miR-200c-alone treatment. This finding suggests that combination with miR-200c mimic can enhance the radiosensitivity of pancreatic tumor cell to carbon ion beams in accompanied with significant tumor cell necrosis, cavitation and fibrosis.

In summary, the combination treatment with carbon-ion beam irradiation and miRNA-200c mimic has advantage to eliminate pancreatic cancer cells containing CSCs accompanied with elevated expression of apoptotic- and autophagic-related genes, *Bax*, *Beclin-1*, and *p62* and decreased expression of angiogenesis-related HIF1 α in vitro and destructed tumor cells in vivo compared to carbon-ion beam irradiation alone.

OncoTargets and Therapy

Dovepress

Publish your work in this journal

OncoTargets and Therapy is an international, peer-reviewed, open access journal focusing on the pathological basis of all cancers, potential targets for therapy and treatment protocols employed to improve the management of cancer patients. The journal also focuses on the impact of management programs and new therapeutic

agents and protocols on patient perspectives such as quality of life, adherence and satisfaction. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
