submit your manuscript | www.dovepress.com Dovepress **Abstract:** Azacitidine (AZA) and decitabine (DAC) are cytidine azanucleoside analogs with clinical activity in myelodysplastic syndromes (MDS) and potential activity in solid tumors. To better understand the mechanism of action of these drugs, we examined the effects of AZA and DAC in a panel of non-small cell lung cancer (NSCLC) cell lines. Of 5 NSCLC lines tested in a cell viability assay, all were sensitive to AZA (EC_{50} of 1.8–10.5 µM), while only H1299 cells were equally sensitive to DAC (EC_{50} of 5.1 µM). In the relatively DAC-insensitive cell line A549, both AZA and DAC caused DNA methyltransferase I depletion and DNA hypomethylation; however, only AZA significantly induced markers of DNA damage and apoptosis, suggesting that mechanisms in addition to, or other than, DNA hypomethylation are important for AZA-induced cell death. Cell cycle analysis indicated that AZA induced an accumulation of cells in sub-G1 phase, whereas DAC mainly caused an increase of cells in G2/M. Gene expression analysis of AZA- and DAC-treated cells revealed strikingly different profiles, with many genes distinctly regulated by each drug. In summary, while both AZA and DAC caused DNA hypomethylation, distinct effects were demonstrated on regulation of gene expression, cell cycle, DNA damage, and apoptosis.

Keywords: apoptosis, azacitidine, decitabine, gene expression, non-small cell lung cancer

Introduction

Azacitidine (AZA) (5-azacytidine, Vidaza[®]; Celgene Corporation, Summit, NJ) and decitabine (DAC) (2'-deoxy-5-azacytidine, Dacogen[®]; Eisai Inc., Woodcliff Lake, NJ) are used clinically for the treatment of myelodysplastic syndromes (MDS), a heterogeneous group of bone marrow stem cell disorders.^{1,2} Both AZA and DAC are cytidine nucleoside analogs that become incorporated into newly synthesized DNA, where they bind DNA methyltransferases (DNMTs) in an irreversible, covalent manner.^{3,4} The sequestration of DNMTs prevents maintenance of the methylation state of DNA, leading to DNA hypomethylation.^{5,6} As a consequence, genes previously silenced by DNA hypermethylation can be re-expressed upon treating cancer cell lines with these DNMT inhibitors.^{7,8} Re-expression of aberrantly methylated genes involved in normal cell cycle control, differentiation, and apoptotic pathways is believed to contribute to the anticancer effects of these drugs.⁹

Clinical activities of AZA and DAC are best established in the hematological malignancies MDS and acute myeloid leukemia (AML), cancers with a high frequency of aberrantly methylated genes.¹⁰ Aberrant DNA methylation of genes involved in DNA repair, cell adhesion, cell cycle, and cell death has also been reported in multiple types of solid cancers, including colon, stomach, breast, ovary, kidney, and lung.¹¹ For example, in non-small cell lung cancer (NSCLC), hypermethylation of tumor suppressor genes RAS association domain family 1A (*RASSF1A*), adenomatous polyposis coli (*APC*), fragile histidine triad (*FHIT*), and *p16*^{INK4A} has been associated with poor survival.^{12–15} Clinical trials investigating the use of AZA and DAC in solid tumors have been reported, although response rates were poor. In a Phase I study of DAC in patients with cancers involving the lungs, esophagus, and pleura, no objective responses were observed.¹⁶ Similar outcomes were obtained with DAC in patients with other forms of solid tumors.¹⁷ In a Phase II trial of AZA in patients with solid tumors, the responses were minimal and transient.¹⁸ The clinical response rate was also low for the combination of AZA and phenylbutyrate in patients with refractory solid tumors.¹⁹

A better understanding of the mechanistic activities of AZA and DAC will provide insights into rational use of these agents as therapies for solid tumor patients, including potential uses as combination therapies, adjuvant therapies, and maintenance therapies. Here, we directly compared the *in vitro* effects of AZA and DAC on cell viability, DNMT1 protein levels, DNA methylation, DNA damage, apoptosis, cell cycle, and gene expression in NSCLC cell lines. Although AZA and DAC caused similar effects on DNA-mediated markers such as DNMT1 depletion and DNA methylation, the drugs showed very different effects on cell viability, DNA damage, apoptosis, cell cycle, and gene expression.

Results

AZA and DAC have differential effects on NSCLC cell viability

AZA and DAC were compared in a panel of 5 NSCLC cell lines (A549, H1975, H460, H23, and H1299) for their effects on cell viability (Figure 1 and Supporting Information Figure 1). AZA reduced cell viability by at least 75% at high concentrations, with EC_{50} values of 1.8–10.5 μ M (Table 1). In contrast, DAC did not reduce cell viability more than 55%, and EC_{50} values were not reached in 4 (A549, H1975, H460, and H23) of the 5 NSCLC cell lines tested. In H1299

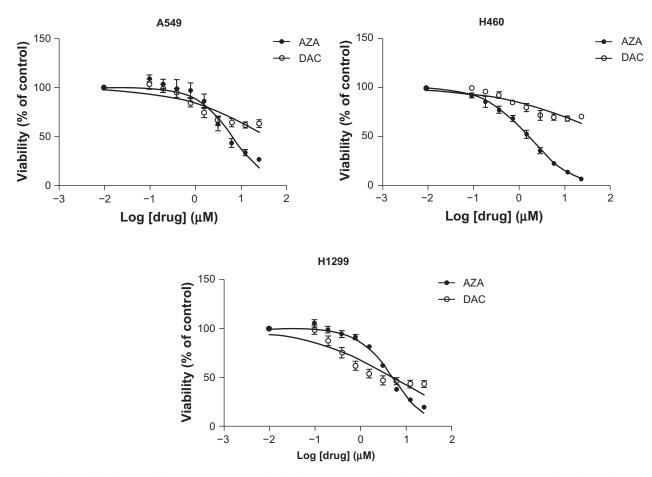

Figure I AZA and DAC differentially affect cell viability in a panel of NSCLC cell lines. Viability of A549, H460, and H1299 cells was assessed after 72 hours of treatment with AZA or DAC (0–25 μM). Error bars represent the standard error of mean of 3 independent experiments, with triplicate wells per experiment. **Abbreviations:** AZA, azacitidine; DAC, decitabine; NSCLC, non-small cell lung cancer.

Table I EC ₅₀ V	values for AZA a	and DAC on NSCL	C cell viability
----------------------------	------------------	-----------------	------------------

	AZA EC ₅₀ ± SEM (μ M)	DAC EC ₅₀ \pm SEM (μ M)
A549	6.3 ± 1.1	>25
H1975	$\textbf{8.6} \pm \textbf{2.9}$	>25
H460	$\textbf{1.8}\pm\textbf{0.3}$	>25
H23	10.5 ± 1.8	>25
H1299	5.1 ± 0.2	$\textbf{5.9} \pm \textbf{2.1}$

Note: EC_{s_0} values were calculated from 3 independent experiments using Graphpad Prism software.

cells, DAC EC₅₀ values were calculated; however, the 95% confidence intervals for the EC₅₀ values were poor (data not shown). The EC₅₀ values for AZA and DAC are similar to those reported for drugs commonly used in NSCLC, including gemcitabine, cisplatin, and carboplatin.^{20–22} The distinct dose-response curves and EC₅₀ values indicate differential sensitivities of these NSCLC cell lines to AZA and DAC.

AZA and DAC cause DNMT1 depletion and DNA hypomethylation

To determine whether the differential sensitivities of NSCLC cell lines to AZA versus DAC in cell viability assays reflected differences in the incorporation of each drug into DNA, DNMT1 protein depletion and DNA hypomethylation were evaluated as indirect measures of drug incorporation into DNA. When A549 and H1299 cells were treated with AZA or DAC for 20 hours, DNMT1 protein levels were reduced (Figure 2). Dose-dependent decreases in DNMT1 protein were observed

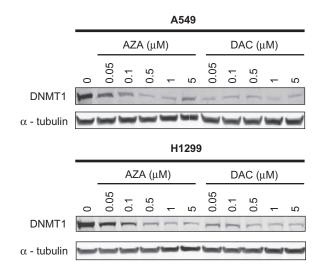

Figure 2 AZA and DAC cause DNMTI depletion in NSCLC cell lines. A549 and H1299 cells were treated with AZA or DAC (0–5 μM) for 20 hours and DNMTI protein was detected by Western blotting of cell extracts. Alpha-tubulin was used as a loading control.

Abbreviations: AZA, azacitidine; DAC, decitabine; DNMTI, DNA methyltransferase I; NSCLC, non-small cell lung cancer. with AZA, while near-maximal reduction of DNMT1 protein was observed at the lowest concentration (0.05 μ M) of DAC. In A549 cells, DNMT1 depletion caused by 5 μ M AZA was not as much as that caused by 0.5 or 1 μ M AZA, possibly as a consequence of cell growth inhibition at the higher AZA concentration.²³ Reduced DNMT1 levels were detected as early as 4 hours after drug treatment (Supporting Information Figure 2). Similar results were obtained in the H460 and H23 cell lines (data not shown).

We next determined whether AZA and DAC caused DNA hypomethylation by examining the methylation status of LINE-1 elements in A549 and H1299 cells treated for 48 hours (Figure 3) or 72 hours (Supporting Information Figure 3). Both AZA and DAC decreased LINE-1 methylation; however, DAC was 3- to 10-fold more potent. Peak hypomethylation was observed at $0.3-1.0 \mu$ M AZA and 0.1μ M DAC. LINE-1 methylation was unaffected at the highest DAC

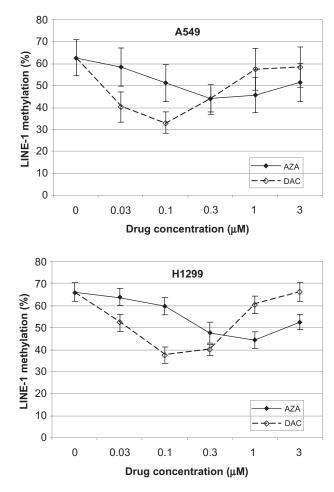

Figure 3 AZA and DAC reduce DNA methylation in A549 and H1299 cells. LINE-1 DNA methylation was assessed in A549 and H1299 cells after 48 hours of treatment with AZA or DAC (0–3 μ M). Percentage LINE-1 methylation represents the average percentage methylation of 4 CpG sites in duplicate samples, with error bars representing the standard deviation.

Abbreviations: AZA, azacitidine; DAC, decitabine.

concentration tested, possibly as a consequence of cell growth inhibition.²³ DAC modulated the DNA-mediated markers (DNMT1 depletion and DNA hypomethylation) in both cell lines, suggesting that the relative insensitivity to DAC in cell viability assays cannot be attributed to a lack of drug uptake, phosphorylation, and DNA incorporation. These findings rule out dysfunctional deoxycytidine kinase, the rate-limiting kinase in the phosphorylation of DAC, as a possible mechanism of relative DAC-insensitivity,²⁴ and suggest that mechanisms in addition to DNA incorporation are responsible for the greater sensitivity of NSCLC cell viability to AZA.

AZA, but not DAC, robustly induces markers of DNA damage and apoptosis

Phase contrast images of A549 cell cultures after 3 days of drug treatment showed reduced cell numbers and increased debris in AZA-treated cell cultures, but healthy-looking cells in DAC-treated cultures (Figure 4). These findings confirmed results of the cell viability assays (Figure 1). To examine the mechanism(s) of drug-induced cell death, A549 and H1299 NSCLC cell lines were treated with AZA or DAC for 24 or 48 hours, and markers of double-strand DNA (dsDNA) damage (histone-H2AX(ser139) phosphorylation) and apoptosis (PARP cleavage) were evaluated by Western blot (Figure 5 and data not shown). AZA dose-dependently induced histone-H2AX(ser139) phosphorylation and PARP cleavage in A549 cells. Similar results were observed in the H460 cell line (data not shown). There was relatively high basal phosphorylation of histone-H2AX(ser139) in H1299 cells, which was further increased by 10 µM AZA.

High concentrations of AZA also induced PARP cleavage in H1299 cells. In A549 and H1299 cells, DNMT1 protein was completely depleted by DAC treatment; however, neither histone-H2AX(ser139) phosphorylation nor PARP cleavage were induced.

As AZA induced PARP cleavage, we further examined early-apoptotic (AnnexinV-FITC⁺ and 7-AAD⁻) and lateapoptotic (AnnexinV-FITC⁺ and 7-AAD⁺) cell populations by flow cytometry in A549 and H1299 cells treated with AZA (3 μ M) or DAC (3 μ M) for 72 hours (Figure 6). AZA (3 μ M) treatment of A549 and H1299 cells caused a significant increase in the early- and late-apoptotic populations (Figures 6B and 6C). DAC did not significantly cause an increase in these populations. These results demonstrated that AZA, but not DAC, induced dsDNA damage and apoptosis in NSCLC cell lines.

DAC-treated H1299 cells show delayed DNA damage response

AZA and DAC appear to be incorporated into DNA of NSCLC cell lines, as both drugs induced DNMT1 depletion (Figure 2) and DNA hypomethylation (Figure 3). It was therefore surprising that 48-hour treatment with DAC did not induce dsDNA damage (histone-H2AX(ser139) phosphorylation) in A549 and H1299 cells (Figure 5). To better define the DNA damage response of NSCLC cell lines treated with AZA and DAC, we treated NSCLC cell lines with the drugs for an extended period of time. A549 and H1299 cells were treated with AZA or DAC for 6 days and lysates were collected on days 3 and 6 (Figure 7). At the 3-day time point in both cell lines, the results were

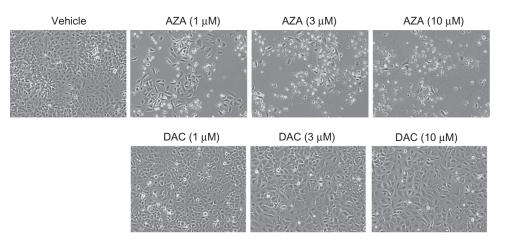

Figure 4 AZA-treated A549 cultures show reduced cell numbers. A549 cells, seeded in 6-well plates, were treated with vehicle or 1, 3, and 10 μ M AZA or DAC for 72 hours. The CoolSNAP ES2 CCD camera (Photometrics) was used to take phase-contrast images of cells under the Plan Fluor 10X objective (Nikon) on the Eclipse Ti-S microscope (Nikon).

Abbreviations: AZA, azacitidine; DAC, decitabine.

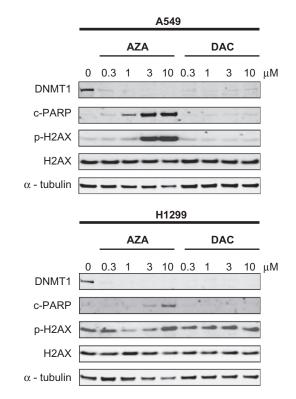

Figure 5 AZA, but not DAC, induces markers of DNA damage and apoptosis in NSCLC cell lines. A549 and H1299 cells were treated with AZA or DAC (0–10 μ M) for 48 hours and Western blotting of cell extracts was used to detect DNMTI, cleaved-PARP, phospho-histone-H2AX(ser139), and total histone-H2AX. alpha-tubulin was used as a loading control.

Abbreviations: AZA, azacitidine; DAC, decitabine; DNMTI, DNA methyltransferase I; NSCLC, non-small cell lung cancer.

similar to those at the 24- and 48-hour time points; AZA, but not DAC, induced histone-H2AX(ser139) phosphorylation and PARP cleavage. In A549 cells, even after 6 days of daily treatment with DAC, there was no induction of histone-H2AX(ser139) phosphorylation and PARP cleavage (Figure 7). The EC_{50} values for AZA and DAC were $4.4 \,\mu\text{M}$ and $2.5 \,\mu\text{M}$, respectively, for A549 cells after 6 days of treatment (Supporting Information Table 1). Although the calculated EC_{50} value for DAC was lower than that of AZA, DAC did not reduce cell viability more than 75%, while AZA almost completely inhibited cell viability (Supporting Information Figure 4). In H1299 cells, substantial histone-H2AX(ser139) phosphorylation, without much effect on PARP cleavage, was observed after 6 days of DAC treatment (Figure 7). Consistent with these results, phase contrast images of H1299 cells treated with DAC for a prolonged period did not show many cells undergoing apoptosis. Rather, prolonged treatment of H1299 cells resulted in fewer cells that are enlarged (data not shown). These results suggest that DAC may have a delayed effect on inducing DNA damage in NSCLC cell lines.

AZA and DAC differentially affect the cell cycle

The effects of AZA and DAC on cell cycle distribution were evaluated in A549 and H1299 cells treated for 72 hours (Figure 8). AZA dose-dependently increased the sub-G1 population in A549 cells, consistent with the induction of apoptosis (Figures 4–6). AZA also caused a minor increase in the sub-G1 population in H1299 cells (Figure 8), consistent with the induction of early-, rather than late-, apoptotic cell population at this time point (Figure 6). DAC also caused a minor increase in the sub-G1 population in these cell lines; however, the more prominent effect of DAC was an increase in the G2/M population.

AZA and DAC modulate expression of different sets of genes

Although both AZA and DAC caused DNMT1 depletion and DNA hypomethylation in NSCLC cell lines, the drugs had very different effects on cell viability, DNA damage, apoptosis, and cell cycle. To better understand the molecular pathways regulated by each drug, A549 and H1299 cells were treated with a dose range (0.3–3.0 μ M) of AZA or DAC for 48 hours, and effects on gene expression were assessed by microarray analysis. The total number of genes regulated by AZA or DAC, and the overlap of regulated genes, are presented in Table 2. At the lower drug concentration (0.3 μ M), AZA and DAC modulated few genes, with DAC modulating 4- to 20-fold more genes than AZA. At the higher drug concentrations (1 and 3 μ M), many more genes were modulated, with AZA typically modulating 2- to 5-fold more genes than DAC. Interestingly, the number of genes modulated in common between the 2 drugs was low (6%-22%). For example, in A549 cells, AZA (3 µM) and DAC (3 μ M) commonly upregulated 66 genes, while AZA uniquely upregulated 636 genes and DAC uniquely upregulated 413 genes (Table 2).

Functional groupings of the modulated genes were determined using Gene Ontology classifications in NextBio. Different biogroups were regulated by each drug. The top 200 biogroups most significantly regulated by each drug (at 3 μ M) are shown in Supporting Information Tables 2–5. In H1299 cells, AZA treatment caused a general downregulation of genes within the "cell cycle", "metabolic process", and "biosynthetic process" biogroups. DAC treatment of H1299 cells caused a general upregulation of genes within the "cell differentiation" biogroup. In A549 cells, AZA treatment

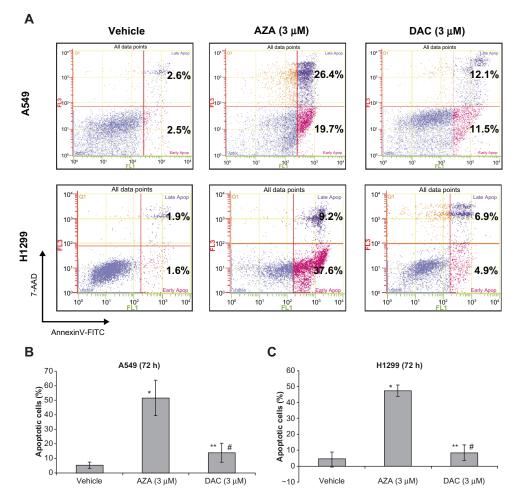

Figure 6 AZA, but not DAC, strongly induces apoptosis in NSCLC cell lines. A549 and H1299 cells were treated with AZA or DAC (3 μ M) for 72 hours, and staining for AnnexinV-FITC (x-axis) and 7-AAD (y-axis) was detected by flow cytometry. **A**) The percentages of early apoptotic cells and late apoptotic cells are represented in the lower right and upper right quadrants, respectively. Representative data of 4 independent experiments are shown. **B**) Percentage (mean ± SD; n = 4) of apoptotic (early and late) cells with AZA or DAC treatment of A549 cells. *P < 0.001 versus "vehicle". *P = 0.328 versus "vehicle". *P < 0.001 versus "AZA (3 μ M)". **C**) Percentage (mean ± SD; n = 4) of apoptotic (early and late) cells with AZA or DAC treatment of H1299 cells. *P < 0.001 versus "vehicle". *P = 0.442 versus "vehicle". *P < 0.001 versus "AZA (3 μ M)".

Abbreviations: AZA, azacitidine; DAC, decitabine; NSCLC, non-small cell lung cancer.

caused downregulation of genes involved in extracellular matrix, while DAC treatment caused downregulation of genes involved in cell cycle. Aside from the regulation of genes related to extracellular matrix, these results are similar to the gene expression data from AML cell lines treated with AZA and DAC.25 Interestingly, AZA treatment of A549 and H1299 cells caused a general upregulation of genes within the "response to DNA damage stimulus" and "DNA repair" biogroups (Figure 9, Supporting Information Tables 2 and 4). These results are consistent with the induction of the dsDNA damage marker (histone-H2AX(ser139) phosphorylation) by AZA in these cells (Figure 5). On the contrary, DAC treatment caused a general downregulation of genes within these biogroups in A549 cells (Figure 9, Supporting Information Table 3), and DAC did not significantly modulate these biogroups in H1299 cells (Supporting Information Table 5). Collectively,

these results indicate that AZA and DAC regulate different cellular pathways.

Discussion

In this study, we revealed differential effects of AZA and DAC on cell viability in a panel of NSCLC cell lines, with AZA inducing greater cellular toxicity and markers of apoptosis (PARP cleavage and AnnexinV staining) in comparison to DAC. Furthermore, AZA induced phosphorylation of histone-H2AX(ser139), a marker of dsDNA damage, while DAC had no, or delayed, effect on this endpoint. The striking differences in the response of NSCLC cell lines to these structurally similar cytidine nucleoside analogs further support emerging evidence that the common perception of these agents as mechanistically interchangeable DNA hypomethylating agents should be reconsidered.^{25,26}

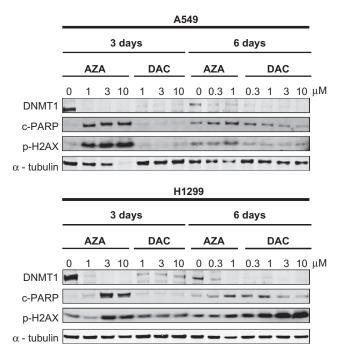

Figure 7 DAC-treated H1299 cells show delayed DNA damage response. A549 and H1299 cells were treated with AZA or DAC (0–10 μ M) for 3 and 6 days, and Western blotting of cell extracts was used to detect DNMT1, cleaved-PARP, and phospho-histone-H2AX(ser139). Alpha-tubulin was used as a loading control. **Abbreviations:** AZA, azacitidine; DAC, decitabine; DNMT1, DNA methyl-transferase I.

Other recent publications also provide data which differentiate AZA from DAC. For example, an *in vitro* study evaluating the response of a panel of human cancer cell lines to AZA and DAC showed no correlation in the EC₅₀ values of the drugs.²⁴ Another study comparing AZA and DAC activity in the Kasumi-1 AML cell line showed that these drugs had distinct and largely non-overlapping effects on gene expression profiles.²⁶ We have recently demonstrated that AZA and DAC have different effects on cell viability, protein synthesis, cell cycle, and gene expression in AML cell lines.²⁵ Similar to the findings in AML cell lines,^{25,26} we now demonstrate notable differences between AZA and DAC effects on NSCLC cell lines.

Despite the differences in the activities of AZA and DAC on cytotoxicity and induction of dsDNA damage, both AZA and DAC were active in modulating the DNA-mediated markers of DNMT1 protein depletion and LINE-1 hypomethylation. While DNA methylation undeniably contributes to cancer development and progression,²⁷ it is not clear that the anticancer effects of cytidine azanucleoside analogs are solely driven by their DNA hypomethylating activity. Findings from several clinical studies suggest that DNA hypomethylation may not correlate with clinical response. For example, a study found that DNMT depletion

caused by DAC treatment did not necessarily result in clinical response.²⁸ Another clinical trial demonstrated that DAC-induced LINE-1 hypomethylation tended to be greater in patients who did not respond to therapy than in patients who did respond.²⁹ Stresemann et al showed that a subset of patients who responded to AZA treatment did not display detectable DNA hypomethylation.³⁰ These results suggest that mechanisms in addition to, or other than, DNA hypomethylation may be critical for the anticancer effects of these drugs.

DAC's potent activity on DNA-mediated markers (DNMT1 depletion and DNA hypomethylation) demonstrates that the lack of cytotoxic activity with DAC was not due to a lack of cellular uptake, drug phosphorylation, and DNA incorporation. It is unclear why DAC does not induce dsDNA damage, despite depleting DNMT1 protein and hypomethylating DNA in the NSCLC cell lines tested. The lack of DAC effects on dsDNA damage and on cytotoxicity is consistent with mounting evidence suggesting that DNA damage may be important for the antitumor effects observed with nucleoside analogs.³¹⁻³⁴ Published data surrounding DAC-induced DNA damage are mixed. In HeLa and HCT116 cells, DAC induced histone-H2AX(ser139) phosphorylation in a DNMT1-dependent and ataxiatelangiectasia-mutated (ATM)-dependent manner;³⁴ however, other researchers found that DAC induced DNA single-strand breaks, but not DNA double-strand breaks (DSBs).^{35–37} Our results suggest that AZA induces DSBs in NSCLC cell lines, coincident with its induction of apoptosis (Figure 5). DAC did not induce as much DSBs and cell death as AZA in A549 cells. Thus, DSBs may correlate with tumor cell death. Dose and schedule will influence mechanism of action, so the potential for cumulative effects of each drug given at low doses or extended schedules should be tested. Furthermore, potential activities of AZA and DAC on cancer stem cell viability and/or differentiation were not tested here.

In summary, we found that AZA and DAC differentially affected the viability of NSCLC cell lines. While AZA and DAC similarly caused DNMT1 depletion and DNA hypomethylation, the drugs differed in their effects on DNA damage, apoptosis, cell cycle, and gene expression. Perhaps a key difference is that AZA can be incorporated into both RNA and DNA, while DAC is only incorporated into DNA.^{25,38–41} The functional consequences of AZA incorporation into RNA can include (1) alterations in the synthesis and processing of various species of RNA, (2) inhibition of transcription, and (3) disruption of protein

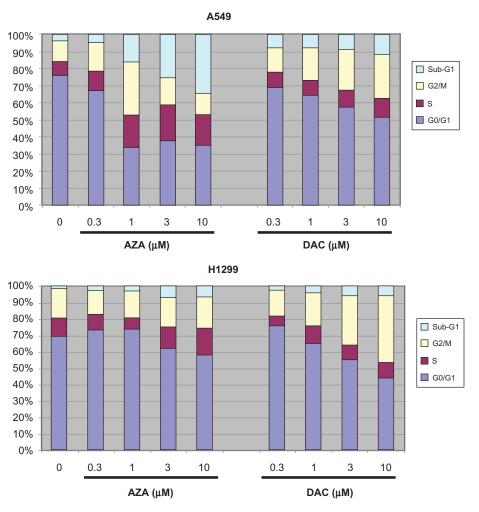

Figure 8 AZA increases the sub-G1 population of cells, while DAC increases the G2/M population. A549 and H1299 cells were stained with NIM-DAPI after 72 hours of treatment with AZA or DAC at 0, 0.3, 1, 3, and 10 μ M. The percentage of cells in sub-G1, G2/M, S, and G0/G1 was quantified by flow cytometry. Representative data of 3 independent experiments are shown. Abbreviations: AZA, azacitidine; DAC, decitabine.

synthesis.^{25,38,42–45} The *in vitro* anticancer activity of AZA in NSCLC models warrants its evaluation in the clinic. It will be important to consider the multiple mechanisms of AZA activity when selecting therapies for use in combination.

Materials and methods Cell culture and drug treatments

NSCLC cell lines (H460, H1299, A549, and H1975) were purchased from American Type Culture Collection (ATCC, Manassas, VA). The H23 NSCLC cell line

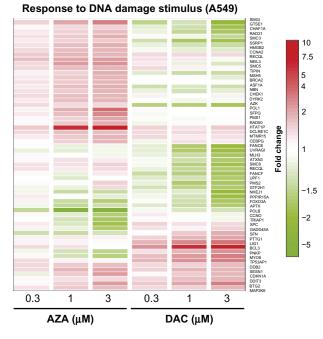

Figure 9 AZA upregulates, while DAC downregulates, genes important in the response to DNA damage stimulus. Gene expression profiling was performed in A549 cells after 48 hours of treatment with AZA or DAC at 0, 0.3, 1, and 3 μ M. NextBio (http://www.nextbio.com/) was used to identify regulated Gene Ontology biogroups from lists of regulated genes. The genes displayed represent all genes within the "response to DNA damage stimulus" biogroup that were modulated 1.7-fold or greater by AZA or DAC.

Abbreviations: AZA, azacitidine; DAC, decitabine.

was obtained from the National Cancer Institute (NCI) (Bethesda, MD). Cell lines were cultured in their respective media, as recommended by ATCC and NCI. AZA was manufactured at Aptuit (Greenwich, CT) for Celgene Corporation, while DAC was purchased from Sigma-Aldrich (St Louis, MO). In all experiments, cells were seeded 24 hours before drug treatment and incubated at 37°C and 5% CO₂. For cell viability assays, H460, H1299, A549, H23, and H1975 cells were seeded in triplicate at 1×10^3 , 1×10^3 , 1×10^3 , 4×10^3 , and 4×10^3 cells per well, respectively, in 96-well plates using 200 µL of medium per well. As the half-lives of AZA and DAC in cell culture are short (~8-12 hours) (data not shown), fresh drug was added every 24 hours by replacing medium with drug-containing medium. For all other assays, cells were seeded at $0.6-1.2 \times 10^5$ cells per well, in 6-well plates, using 4 mL of medium per well, with fresh drug added directly to the medium every 24 hours. At this seeding density, cells are 30%-40% confluent at the start of drug treatments. The concentrations of AZA and DAC used in these experiments are similar to the maximum concentrations (Cmax) achieved in human plasma at clinically used dosages and schedules of administration (3-11 µM AZA and 0.3-1.6 µM DAC).28,46,47

Cell viability

Cell viability was assessed 72 hours after the initial drug treatment, using the CyQUANT assay (Life Technologies Corporation, Carlsbad, CA). Fluorescence was measured with a spectrophotometer (Molecular Devices, Sunnyvale, CA), and EC_{50} values were calculated from three independent experiments using Prism version 5.01 (GraphPad Software, Inc., La Jolla, CA).

Western analysis

For Western analyses of protein levels, cells were washed with phosphate-buffered saline (PBS) and lysed with radio immuno precipitation assay (RIPA) buffer (Cell Signaling Technology, Inc., Danvers, MA) supplemented with 350 mM NaCl and 0.1% sodium dodecyl sulfate (SDS). Cell lysates were sonicated with two 5-second bursts under low amplitude (20%) using the Digital Sonic Dismembrator (ThermoFisher Scientific, Inc., Waltham, MA). Proteins were separated on 4%-12% Bis-Tris NuPAGE gels (Life Technologies Corporation) and transferred to nitrocellulose membranes. DNMT1, phospho-histone-H2AX(ser139), total histone-H2AX, cleaved-PARP, and alpha-tubulin were detected using the Li-Cor Odyssey imaging system (Li-Cor Biotechnology, Lincoln, NE), following incubation with the appropriate primary and secondary antibodies. The phospho-histone-H2AX(ser139) and cleaved-PARP antibodies were obtained from Cell Signaling Technology, Inc. The total histone-H2AX (C-20) antibody was purchased from Santa Cruz Biotechnology, Inc. (Santa Cruz, CA). The alpha-tubulin and DNMT1 antibodies were purchased from EMD Chemicals, Inc. (Gibbstown, NJ) and Abcam, Inc. (Cambridge, MA), respectively. The goat anti-Rabbit IRDye 680, goat anti-Mouse IRDye 800CW, and donkey anti-Goat IRDye 800CW secondary antibodies were obtained from Li-Cor Biotechnology.

DNA methylation analysis

Genomic DNA was purified from cells using the DNeasy Blood and Tissue Kit (Qiagen, Valencia, CA), according to the manufacturer's instructions. DNA yield was quantitated with a NanoDrop 8000 spectrophotometer (ThermoFisher Scientific, Inc.). Genomic DNA (1 μ g/sample) was submitted to EpigenDx (Worcester, MA) for bisulfite conversion and pyrosequencing of LINE-1 elements. Briefly, 1 μ g of DNA was bisulfite treated using the Zymo DNA Methylation Kit (Zymo Research, Orange, CA) and eluted in 10 μ L volume. DNA eluate (1 μ L) was used for polymerase chain reaction (PCR) with biotinylated primers to the LINE-1 locus, converting the PCR product to single-stranded DNA templates. PCR products (each $10 \ \mu L$) were sequenced by the Pyrosequencing PSQ96 HS System (Biotage AB), following the manufacturer's instructions (Biotage, Kungsgatan, Sweden). The methylation status of each locus was analyzed individually as a T/C SNP using QCpG software (Biotage). Percentage LINE-1 methylation represents the average percentage methylation of 4 CpG sites in duplicate samples. EpigenDx provided 3 controls for the LINE-1 methylation assay: (1) low methylated DNA control, which is human genomic DNA that has been chemically and enzymatically treated to remove the methyl groups; (2) high methylated DNA control, which is human genomic DNA that has been methylated in vitro; and (3) 50/50 mix control, which is an equal mixture of the low methylated DNA and high methylated DNA controls. The percentages of LINE-1 methylation for the low methylated DNA control, the 50/50 mix control, and the high methylated DNA control were 25.8 ± 8.1 , 56.2 ± 4.6 , and 86.3 ± 6.5 , respectively (data not shown).

Flow cytometry

For cell cycle distribution, cells were stained with the NIM-DAPI reagent (Beckman Coulter, Inc., Fullerton, CA). For measurement of early- and late-apoptotic cell populations, cells were stained with AnnexinV-FITC and 7-AAD reagents (Beckman Coulter, Inc.). Samples were processed according to manufacturer's instructions and analyzed on a Cell Lab Quanta MPL flow cytometer (Beckman Coulter, Inc.). The effects of treatment were compared using one-way ANOVA, followed by single step method for adjusting *P*-values in multiple testing with the bioconductor package multcomp.⁴⁸

Gene expression analysis

Cells were lysed using the TRIzol reagent (Life Technologies Corporation), and total RNA was isolated using the miRNeasy kit (Qiagen). Double-stranded cDNA and biotinlabeled cRNA were synthesized using 100 ng of total RNA with Ambion's MessageAmp Premier RNA Amplification Kit (ABI, Foster City, CA). Biotin-labeled cRNA (10 μ g) was fragmented and hybridized to each human U133A 2.0 genechip (Affymetrix, Santa Clara, CA). The GC-RMA algorithm was used for normalization, and all analyses were done using GeneSpring 7.3 (Agilent, Santa Clara, CA). Averaged signals from biological duplicate samples were used to determine fold change (treated versus untreated), with an absolute fold change of \geq 1.7 defining regulated genes. NextBio (http://www.nextbio.com/) was used to identify regulated gene ontology biogroups from lists of regulated genes. The top 200 biogroups are those with the lowest *P*-values calculated within NextBio.

Acknowledgments

We would like to acknowledge Sharon Aukerman, Victoria Sung, and Sharianne Louie for critical review of the manuscript. We thank Gina Fusaro and Marianna Shafarenko for their assistance with manuscript editing. We also thank Xiaoyue Zhao for statistical analyses. Vidaza is a marketed product with azacitidine as the active pharmaceutical ingredient. Dacogen is a marketed product with decitabine as the active pharmaceutical ingredient.

Disclosure

ANN, PWH, NR, AL-M, HB, CH, and KJM are employees of Celgene and as such own stock in the company.

Supporting information figures and tables

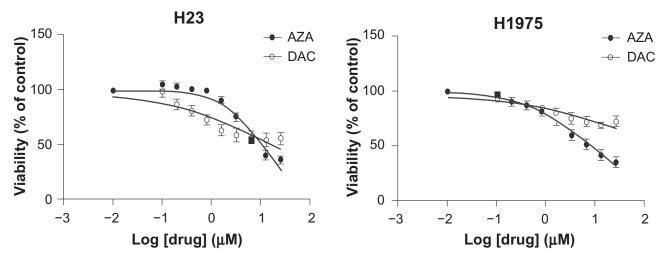

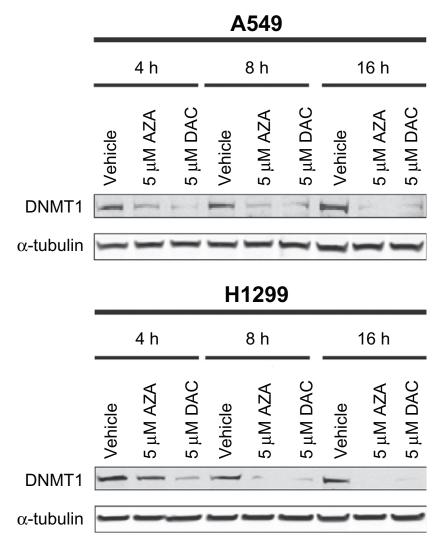

Figure S1 Viability of H23 and H1975 cells was assessed after 72 hours of treatment with AZA or DAC (0–25 μ M). Error bars represent the standard error of mean of three independent experiments, with triplicate wells per experiment.

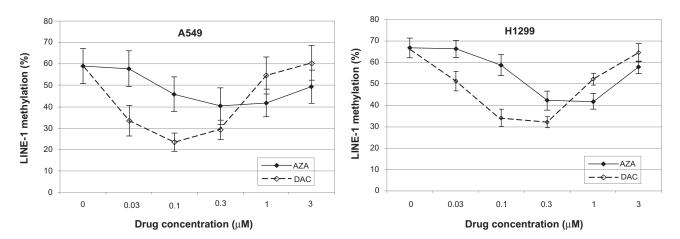

Figure S3 AZA and DAC reduce DNA methylation in A549 and H1299 cells. LINE-1 DNA methylation was assessed in A549 and H1299 cells after 72 hours of treatment with AZA or DAC (0–3 μ M). Percentage LINE-1 methylation represents the average percentage methylation of 4 CpG sites in duplicate samples, with error bars representing the standard deviation.

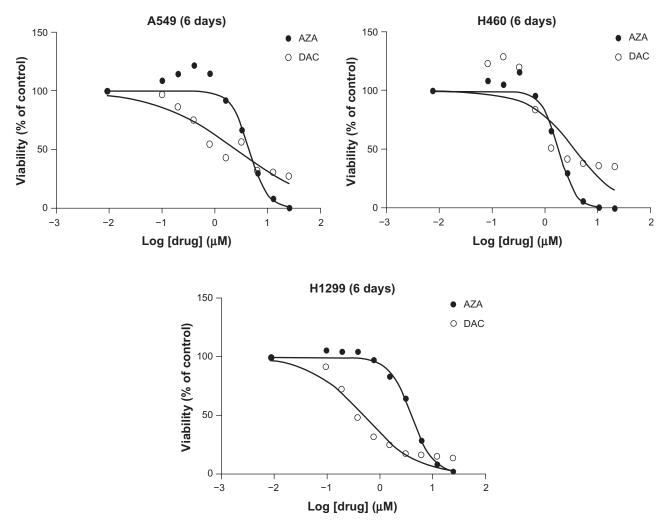

Figure S4 Viability of A549, H460, and H1299 cells was assessed after 6 days of treatment with AZA or DAC (0-25 μM).

 Table SI EC₅₀ values for AZA and DAC on NSCLC cell viability
 Table S2 (Continued)
 (6 days)

AZA EC ₅₀ (μM)		DAC EC ₅₀ (μ M)		
A549	4.4	2.5		
H460	2.2	4.4		
H1299	4.1	0.5		

Abbreviations: AZA, azacitidine; DAC, decitabine; NSCLC, non-small cell lung cancer.

Table S5 (Continued)

Biogroup name	Direction	P value
	down	2.60E-0
Oxidoreductase activity, acting on the CH–CH group of donors, NAD or NADP as acceptor	dowii	2.00E-0
Death	up	3.20E-0
Cell death	up	3.20E-0
Steroid metabolic process	down	3.50E-0
Lipid biosynthetic process	down	3.80E-0
Lyase activity	down	4.10E-0
Glycosaminoglycan binding	up	4.50E-0
Polysaccharide binding	up	5.30E-0
Pyridoxal phosphate binding	down	5.50E-0
Muscle development	up	6.70E-0
Nitrogen compound biosynthetic process	down	6.90E-0
Protease inhibitor activity	up	7.60E-0
Endopeptidase inhibitor activity	up	7.60E-0
Phosphatase activator activity	up	8.00E-0
Phenol metabolic process	up	8.40E-0
Epidermis development	-	8.50E-0
Regulation of neurotransmitter levels	up	9.20E-0
-	up	
Pattern binding	up	9.60E-0
Cofactor catabolic process	down	9.80E-0
Positive regulation of developmental process	up	1.00E-0
Vitamin binding	down	0.0001
Oxidoreductase activity, acting on the	down	0.0001
CH–CH group of donors		
Amino acid derivative metabolic process	up	0.0001
Chromatin assembly	up	0.0001
Protein–DNA complex assembly	up	0.0001
Amino acid derivative biosynthetic process	up	0.0001
Positive regulation of cell differentiation	up	0.0001
Acute inflammatory response	up	0.0001
Dopamine metabolic process	up	0.0001
Growth factor binding	up	0.0002
Endothelial cell development	down	0.0002
Transcription corepressor activity	up	0.0002
Keratinocyte differentiation	up	0.0002
Ectoderm development	•	0.0002

Extracellular matrix structural constituent		0.0011	kinase activity		
	up		Outer membrane-bounded periplasmic space	down	
Dxidoreductase activity, acting on the	down	0.0012	Cell envelope	down	
aldehyde or oxo group of donors		0.0010	Axon	up	
Biogenic amine metabolic process	up	0.0012	Transferase activity, transferring hexosyl groups	down	
pidermis morphogenesis	up	0.0013	Energy derivation by oxidation of organic	down	
Endothelial cell differentiation	down	0.0013	compounds		
Endoplasmic reticulum	down	0.0013	Response to reactive oxygen species	up	
Carbon–oxygen lyase activity	down	0.0013	Meiosis	up	
Germ cell development	up	0.0014	Meiotic cell cycle	up	
Cell proliferation	down	0.0015	Enzyme activator activity	up	
Peroxidase activity	up	0.0015	Hemopoiesis	up	
Oxidoreductase activity, acting on peroxide	up	0.0015	Positive regulation of biosynthetic process	up	
as acceptor			Regulation of transforming growth factor	down	
Specific RNA polymerase II transcription	up	0.0015	beta receptor signaling pathway		
actor activity			FAD binding	down	
Positive regulation of programmed cell death	up	0.0016	Negative regulation of growth	down	
Response to nutrient levels	down	0.0016	Defense response to Gram-positive bacterium	up	
Ayeloid cell differentiation	up	0.0016	Sensory perception of light stimulus	down	
Lung development	up	0.0017	Catabolic process	down	
Dxidoreductase activity, acting on paired	down	0.0017	Hemopoietic or lymphoid organ development		
donors, with incorporation or reduction	30001	0.0017		up	
-			Positive regulation of protein metabolic process	up	
of molecular oxygen		0.0017	Intermediate filament	up	
/asculature development	up	0.0017	Ras GTPase activator activity	down	

Table S5 (Continued)

HI299 cells treated with 3 μM DAC (48 hours)

Biogroup name	Direction	P value			
Response to nutrient	down	0.0053			
Protein kinase regulator activity	up	0.0053			
Carbohydrate binding	up	0.0054			
Calcium ion binding	down	0.0055			
Oxidoreductase activity, acting on sulfur	down	0.0056			
group of donors					
Response to hypoxia	down	0.0057			
Transferase activity, transferring aldehyde or	up	0.0058			
ketonic groups					
Positive regulation of multicellular organismal	up	0.0059			
process					
Xenobiotic transporter activity	up	0.0063			
Xenobiotic-transporting ATPase activity	up	0.0063			
Phospholipase inhibitor activity	up	0.0064			

Notes: Functional groupings of the modulated genes were determined using Gene Ontology classifications in NextBio. The top 200 biogroups most significantly regulated by DAC (at 3 μ M) are shown.

Lung Cancer: Targets and Therapy

Publish your work in this journal

Lung Cancer: Targets and Therapy is an international, peer-reviewed, open access journal focusing on lung cancer research, identification of therapeutic targets and the optimal use of preventative and integrated treatment interventions to achieve improved outcomes, enhanced survival and quality of life for the cancer patient. Specific topics covered in the journal include:

Submit your manuscript here: http://www.dovepress.com/lung-cancer-targets--therapy-journal

Dovepress

Epidemiology, detection and screening; Cellular research and biomarkers; Identification of biotargets and agents with novel mechanisms of action; Optimal clinical use of existing anticancer agents, including combination therapies; Radiation and surgery; Palliative care; Patient adherence, quality of life, satisfaction; Health economic evaluations.
