Sphenoethmoidal mucocele presenting with unilateral visual loss

Background: Sphenoethmoidal sinus mucocele causing uniocular progressive vision loss is a rare entity and was first described by Bery in 1985. It is generally diagnosed in its advanced stage when the patients develop subjective ophthalmic symptoms.

Case: A 43-year-old male presented to our institute for further evaluation and treatment of progressive visual deterioration in his left eye. The patient complained of visual impairment in his left eye for the past three months, in the form of a dark area in his left side of the visual field.

Observations: Magnetic resonance imaging (MRI) revealed a large expansile lesion in the left sided posterior ethmoidal air cells, abutting on the left optic nerve and displacing it in the region of the orbital apex. The patient underwent an urgent endoscopic sinus surgery by an Ear-Nose-Throat surgeon which resulted in stable visual acuity in the sixth postoperative month.

Conclusions: Sphenoethmoidal mucocele can cause irreversible blindness. Progressive vision loss with a neurological visual field defect should raise a high index of suspicion and computed tomography and MRI are to be performed to confirm the diagnosis. Collaboration between radiologists, ENT specialists, and ophthalmologists is essential for treating such cases.

Case

A 43-year-old man was referred to our institution in November 2008 for further evaluation and treatment of progressive visual deterioration out of retrobulbar neuritis in the left eye in spite of diagnosis and treatment with intravenous methylprednisolone at another medical centre. He complained of visual impairment in the left eye for the past three months, in the form of a dark area in his left side of the visual field. His medical and family history was unremarkable.

Observation

On examination, his visual acuity was 20/20 in the right eye and 20/30 in the left eye. Ocular movements were normal but relative afferent pupillary defect was present in the left eye. Fundus examination revealed generalized optic disc pallor, a well demarcated disc margin, and dilated retinal venules in the left eye (Figure 1). Computerized visual field analysis detected gross loss of threshold sensitivity except in the inferonasal quadrant where some sensitivity was retained (Figure 3), while the right eye was clinically normal. Urgent MRI disclosed a large expansile T2 hyperintense lesion in the left side posterior ethmoid air cells encroaching the adjacent sphenoid sinus (Figure 4). On T1-weighted images the lesion showed significant hyperintensity (Figure 5). The rest of the sphenoid sinus also contained mixed intensity components expressing hyperintense and hypointense signals. The lesion was abutting on the left optic nerve which was displaced in the region of orbital apex with narrowing of the superior orbital fissure. Depending upon the clinical and investigation findings, left compressive optic neuropathy caused by left sphenoid sinus mucocele was diagnosed and the patient underwent urgent endoscopic sinus surgery. Marsupialization of the mucocele was performed under general anesthesia, in which the anterior and interior walls (septum) of the mucocele were removed. Pathological examination confirmed diagnosis of a mucocele. At the sixth month postoperative follow up, vision was stable with persistent disc pallor (Figure 6). Humphrey field analysis detected paracentral scotoma (30-2 tests; Figure 7) in left eye. MRI revealed minimal residual collection of fluid in the mucocele (Figure 8), however there was no compression to the optic nerve.

Discussion

Sphenoid sinus mucocele is a rare cause of unilateral vision loss and blindness. Both genders are equally affected without any age predominance.1–7 Clinical examination and imaging (CT and MRI) are the bases of diagnosis. Clinical
manifestations of sphenoid mucoceles are usually related to sinus expansion and extension of the lesion beyond the confines of the sinus. The extension of the lesion usually follows the path of least resistance.

The presenting signs and symptoms are variable. If complication occurs, the most frequently reported findings are headache (89%), decreased visual acuity (57%), abduc-ent or oculomotor palsies (56%), and exophthalmos (25%).

Optic neuropathy is a well known complication of paranasal sinusitis and mucoceles.7,8 Different levels of vision loss including blindness can occur secondary to optic nerve dysfunction. One eye involvement is common particularly along with mucocele in the posterior paranasal sinus.2

There is a double mechanism involved in the development of visual loss caused by a mucocele.7,9 A gradual loss of vision is caused by circulatory disorders of the optic nerve due to pressure affect of the mucocele. Because the vascular supply of the optic nerve in the optic canal is limited and less dense than it is in other regions, this is a site where the optic nerve is susceptible to vascular compromise.10 On the other hand, a rapid loss of vision occurs from spread of infection and/or inflammation from the mucocele to the optic nerve.10

We presented a case of progressive deterioration of vision, neurological visual field defect, and VEP abnormality of the left eye. MRI findings showed left sphenoid mucocele causing compression of the left superior orbital fissure, orbital apex, and displacement of the same sided optic nerve which led to confirmation of the diagnosis. Our case had atypical presentation because other presenting common features like headache, abduc-ent or oculomotor nerve palsies, or exophthalmos were absent. As a result of this diagnostic dilemma, the patient received intravenous methylprednesolone without any result in another medical centre. Along with the above findings, generalized disc pallor and mild venous stasis support the compressive
theory of vision loss by the sphenoethmoidal mucocele. Thus, transnasal endoscopic surgical decompression is the standard surgical management of such cases and was carried out by an ENT surgeon for our patient. In the postoperative period, there was no further loss of vision.

Sphenoethmoidal sinus mucoceles can cause bilateral or even irreversible blindness and overall surgical prognosis may not be good.6 Ophthalmologists must be alert to this diagnosis. Progressive vision loss in one eye with a neurological visual field defect should raise a high index of suspicion and CT and MRI imaging need to be performed to confirm the diagnosis. Close collaboration between radiologists, ENT specialist, and ophthalmologists is essential for treating such cases.
