Value of PTEN and Echocardiography in Predicting the Efficacy of Trimetazidine Combined with Metoprolol in the Treatment of Heart Failure

Objective: To investigate the predictive value of PTEN and echocardiography in the treatment of heart failure with trimetazidine combined with metoprolol.

Methods: A total of 100 patients with coronary heart disease and HF who admitted to our hospital from August 2018 to August 2020 were enrolled into research. All patients received routine treatment according to the guidelines and were treated with trimetazidine and metoprolol for a total course of 6 months. Echocardiographic parameters and PTEN levels were measured at baseline and after treatment. The patients were divided into groups according to the quartile of basic PTEN level, and the total effective rates were compared. The echocardiographic parameters of patients with different prognosis were analyzed. Bivariate correlation analysis was used to evaluate the correlation between PTEN, echocardiography and treatment effect.

Results: Compared with that before treatment, the level of PTEN increased significantly after treatment (P < 0.01). According to the quartile of basic PTEN level, the total effective rate of patients with different levels of basic PTEN was was statistically different (P < 0.01). There was a linear correlation between the level of basic PTEN and the treatment effect, and the total effective rate of patients with high level of basic PTEN was higher than that of patients with low level of PTEN. Compared with before treatment, LVEF, SV, E/A and lvfs increased significantly after treatment (P < 0.01). There was a correlation between the basic echocardiographic parameters and the treatment effect of patients. The basic echocardiographic parameters of patients with poor prognosis were worse than those with good prognosis. PTEN expression in patients’ serum was only positively correlated with E/A, but not with LVFE, SV and LVFS (P < 0.01).

Conclusion: PTEN and echocardiographic parameters serve as a good method to evaluate the short-term therapeutic effect of trimetazidine combined with metoprolol in patients with heart failure.

Keywords: PTEN, echocardiographic parameter, heart failure, trimetazidine, metoprolol, efficacy prediction

Introduction

Heart failure (HF) is a familiar heart disease. It is very common in patients who die from HF all over the world. Recently, with aging world arriving, the incidence is also increasing.1,2 It’s reported that the prevalence rate of HF is 3.1/1000; the morbidity has been increasing.3 HF can cause respiratory failure, hemoptysis, insomnia and nervous system diseases to some degree, and there are risks of sudden death in severe cases.4,5 Thus, HF diagnosis and treatment is crucial to the lives and health of patients.
Myocardial fibrosis will cause imbalance of type I/III collagen, which will increase left ventricular stiffness, reduce compliance, and limit diastolic left ventricular filling; if the degree of myocardial fibrosis in patients continues to deepen, it will damage the systolic function of myocardium and greatly reduce the cardiac output. Echocardiography, as a non-invasive examination method, is easily accepted by patients; but it is difficult to make an accurate judgment on the distribution of myocardial fibrosis, because its detection results are easily influenced by subjective factors of operators. It has been found that echocardiography combined with biomarkers can improve the diagnosis rate of HF patients. PTEN (phosphatase and tensin homolog deleted on chromosome 10) is a tumor suppressor gene discovered early. Research has shown that PTEN regulates cell growth and apoptosis. For example, PTEN can adjust Akt activity by inhibiting PI3K, and play a regulatory role in apoptosis. PTEN modulation by hexarelin attenuates coronary artery ligation-induced HF in rats. However, whether PTEN has clinical value in HF has not been verified yet.

Trimetazidine combined with metoprolol is effective in the treatment of coronary heart disease and heart failure, serving as one of the commonly used clinical schemes. Here, in this study, we mainly explored the changes of PTEN and echocardiographic parameters after treatment in HF patients, and the potential predictive value of efficacy, aiming to provide reference indicators for clinical treatment and efficacy prediction.

Methods and Data
Clinical Data
100 patients with coronary heart disease and HF who admitted to our hospital from August 2018 to August 2020 were enrolled into research. This experiment has been ratified by the Ethics Committee of Second Hospital of Wuxi Affiliated to Nanjing Medical University, all methods were performed in accordance with the Declaration of Helsinki, and all the participants have signed informed consent forms.

Inclusion and Exclusion Criteria
Inclusion criteria: Over 45 years old; conformed to the clinical manifestations of chronic heart failure; diuretics, beta-receptor-blocking agent and spironolactone were given according to the 2014 Chinese guidelines for the diagnosis and treatment of heart failure; the cardiac function were grade III ~ IV according to New York Heart Association (NYHA); echocardiography showed left ventricular ejection fraction (LVEF) < 50%.

Exclusion criteria: Patients with other cardiovascular and cerebrovascular diseases, immune deficiency diseases, infectious diseases, mental disorders and tumor diseases; those with liver and kidney organ dysfunction; those with drug allergy; those who received surgery, radiotherapy and chemotherapy, and antibiotics within six months prior to admission; those transferred.

Therapeutic Regimens
After admission, all patients were given routine treatment intervention, including diuretics, nasal catheter oxygen inhalation, cardiotonic agents, correction of water and electrolyte disorders, and blood lipid lowering and vasodilatory drugs. On this basis, trimetazidine and metoprolol were used. The dosage of metoprolol tartrate tablets was 6.25 mg/time, 3 times/d for the first time. After 14 days of treatment, the dosage should be appropriately increased or decreased according to patients’ actual condition and recovery. It can be increased once every 7 days to 6.25–12.5 mg. The defined daily dose should be controlled within 300 mg. In like wise, trimetazidine hydrochloride tablets should be 20 mg/time, orally, 3 times/d, for a total of 6 months.

Ultrasonic Testing
The patient was examined by an experienced sonographer, with left lateral position. The left ventricular end systolic diameter (LVESD) and left ventricular end diastolic diameter (LVEDD) were obtained through the parasternal long axis section of the left ventricle with PHILIPS HD 11 echocardiography and C5-2 probe (frequency 2.0~5.0 MHz). What’s more, the left ventricular ejection fraction (LVEF) was calculated. The mitral E/A ratio was obtained by apical four-chamber section, and the results were averaged after 3 tests. The rate of left ventricular fractional shortening (LVFS) was tested by M-mode echocardiography.

PTEN Expression
QRT PCR was used. The serum to be tested was obtained; the total RNA was separated through TRIZol (Invitrogen, USA), and then 5 μL was used to test its integrity under agarose gel electrophoresis. According to the reverse transcription kit instructions (BIOMIGA, USA), the total RNA was reverse transcribed into cDNA, and qRT-PCR was
performed with GAPDH as internal reference (primer sequence, Invitrogen, USA) (Table 1). Reaction conditions: 95°C for 10 min, followed by 40 cycles of 95°C for 15 s and 60°C for 1 min. The reaction system: cDNA product 2 μL, 50×ROX reference dye 0.4 μL, SYBR qPCR Mix 10 μL, upstream and downstream primers 0.8 μL each, and RNase water made up to 20 μL. The circulation threshold (ct value) of the target gene and internal reference was read, and the relative level of the former in the sample was expressed by $2^{-\Delta\Delta Ct}$.

Efficacy Evaluation
According to the cardiac function at discharge, it can be divided into obvious improvement (cardiac function after treatment improves by more than 2 grades), general improvement (cardiac function after treatment improves by 1 grade), no improvement (no improvement of cardiac function after treatment) and deterioration (aggravation of heart failure, deterioration or death after treatment). Total effective = obvious improvement + general improvement.

Statistical Analysis
All the data were statistically analyzed by SPSS22.0 statistical software. The relevant pictures were drawn by GraphPad 8 software. The average value was obtained after 3 repetitive tests, recorded as (mean±standard deviation). The comparison between groups was carried out by independent-samples t-test, including t value and $P$ value. According to the basic PTEN level grouping, the two-way ordered classification data linear trend test was used to compare the improvement of the overall clinical status of patients with different prognosis after treatment. Logistic regression model was used to evaluate the predictive value of PTEN and echocardiography on the efficacy of trimetazidine combined with metoprolol in the treatment of heart failure. $P$ value of <0.050 is considered as statistical difference.

Results
Comparison of Basic Data of Patients with Different Prognosis
Among 100 HF patients, there were 58 males and 42 females, aged from 48 to 68 years, with an average age of (60.13±5.84) years, 55 cases of hypertension, and 58 cases of diabetes. After treatment of trimetazidine combined with metoprolol, there were 34, 38, 26, 2 cases of obvious improvement, general improvement, no improvement and deterioration respectively. There was no significant difference in the basic data of patients with different prognosis ($P > 0.05$). Table 1

Expression of PTEN in HF Patients
Compared with before treatment, the level of PTEN increased significantly after treatment ($t = 24.284$, $P < 0.01$). The basic PTEN level of the included patients was $0.21 \sim 0.76$ [0.47 (0.63)]. According to the quartile of basic PTEN level, they were divided into ≤ 0.34 group (23 cases), 0.35 ~ 0.53 (29 cases), 0.54 ~ 0.64 (30 cases) and ≥ 0.65 (18 cases). The total effective rates of patients with different levels of basic PTEN were compared, and the difference was statistically significant ($P < 0.01$). The linear trend test results of ordered grouping data showed that there was a linear correlation between the basic PTEN level and the treatment effect of patients ($\chi^2_{\text{total}} = 16.372$, $P = 0.031$; $\chi^2_{\text{Regression}} = 9.684$, $P = 0.014$; $\chi^2_{\text{bias}} = 5.382$, $P = 0.46 \sim 0.78$). The total effective rate of patients with high level of basic PTEN was higher than that of patients with low level of PTEN.

Figure 1, Table 2
Echocardiographic Parameters in HF Patients

Compared with before treatment, LVEF, SV, E/A and LVFS increased significantly after treatment ($t = 21.324, 19.463, 24.673, P < 0.01$). The linear trend test of ordered grouping data showed that there was a correlation between basic echocardiographic parameters and treatment effect ($\chi^2_{\text{total}} = 11.674, P = 0.035; \chi^2_{\text{Regression}} = 14.275, P = 0.018; \chi^2_{\text{bias}} = 8.928, P = 0.32 \sim 0.76$). The basic echocardiographic parameters of patients with poor prognosis were worse than those with good prognosis. Figure 2, Table 3

Correlation Between PTEN and Echocardiographic Parameters

At the end of the study, we analyzed the relationship between serum PTEN and echocardiographic parameters in HF patients. Through analysis, we found that PTEN expression in patients’ serum was only positively correlated with E/A, but not with LVFE, SV and LVFS (Figure 3, $P<0.05$).

Discussion

Drug therapy is the main treatment for coronary heart disease and HF, but the efficacy of conventional drugs is not good. Further improving the science and rationality of medication is of great significance to improving the effectiveness of treatment. Metoprolol is a commonly used clinical $\beta_1$-receptor blocker and a first-line antihypertensive drug. Compared with other anti-angina pectoris drugs, trimetazidine has less effect on myocardial hemodynamics, and can significantly improve endothelial function in patients with heart failure and relieve clinical symptoms. Relevant studies have shown that metoprolol combined with trimetazidine has a significant effect in the treatment of patients with coronary heart disease and HF, and can effectively improve the hemodynamics of patients. In this study, we examined the predictive value of PTEN and echocardiographic parameters in HF patients after treatment. PTEN is a bifunctional phosphatase, which can dephosphorize lipid and protein. It negatively regulates PI3K pathway by dephosphorizing phosphatidylinositol triphosphate and pAkt, thus regulating apoptosis and cell proliferation pathway. Furthermore, recent research has demonstrated that PTEN down-regulation can participate in smooth muscle cell (SMC) proliferation and vascular remodeling, which is considered to be involved in the occurrence of cardiac fibrosis after myocardial infarction. Echocardiography is the most common clinical method for evaluating cardiac function, which is rapidly popularized because of its non-invasive, simple, repeatable and relatively low cost. The comprehensive parameters of echocardiography include many factors, such as cardiac systolic function, cardiac diastolic function, ventricular remodeling, valve regurgitation, pulmonary artery pressure, etc.; considering the mutual influence and action among various parts, the evaluation result is not

a simple numerical accumulation, but an overall evaluation of cardiac function made by integrating the changes of various parts of the heart.\textsuperscript{20} We also found that compared with before treatment, PTEN levels increased significantly after treatment, suggesting that PTEN and echocardiographic parameters may be related to the occurrence of heart failure. And compared with before treatment, LVEF, SV, E/A, and LVFS were significantly increased after treatment, which was in line with the results of previous studies, suggesting that metoprolol combined with trimetazidine may affect PTEN levels and improve patients’ heart function. Early prognosis evaluation is a crucial means to improve the efficacy and prognosis of patients. Afterwards, patients choose a more favorable treatment plan, which can effectively control the disease, speed up the recovery, and avoid poor efficacy or prognosis caused by untimely treatment.\textsuperscript{21} Here, we divided the patients into groups according to their clinical efficacy after treatment.

Based on the quartile of basic PTEN level, we found that the total effective rate of patients with high basic PTEN level was higher than that of patients with low basic PTEN level, suggesting that patients with high basic PTEN level may have a better prognosis, which can provide a reference for the formulation of clinical treatment plan; the basic echocardiographic parameters of patients with poor prognosis were worse than those with good prognosis, indicating that echocardiographic parameters are expected to become a potential index to predict the clinical efficacy of patients. The main feature of ventricular remodeling after myocardial infarction is that in the initial stage, myocardial cell death and inflammation around and in the infarcted area increase, leading to myocardial hypertrophy and fibrosis, which is considered to be a key process involved in the pathophysiology of HF. Early studies have suggested that PTEN deletion brings about myocardial hypertrophy. We believe that HF patients with low PTEN expression predict myocardial fibrosis and hypertrophy, which is not conducive to the improvement of patients’ condition. The E/A ratio is one of the indexes for the auxiliary diagnosis of HF with normal left ventricular ejection fraction; have verified that the ratio is used to evaluate essential hypertension with HF and hypertension-induced left ventricular hypertrophy. Through correlation analysis, we also determined that there was a positive correlation between PTEN and E/A, which further indicates that PTEN is expected to become a predictor of efficacy in HF patients.

Besides, we confirmed the predictive value of PTEN and echocardiographic parameters in HF patients after treatment. In this study, we found that PTEN expression in patients’ serum was only positively correlated with E/A, but not with LVFE, SV and LVFS. But, this study still has some limitations. First of all, this study did not conduct a retrospective study of large samples. Thus, we hope to verify the study through large sample data. Secondly, this study did not analyze the mechanism of PTEN in HF. We hope to carry out basic research in the follow-up study to determine the mechanism.

Above all, PTEN and echocardiographic parameters can better evaluate the short-term therapeutic effect of
trimetazidine combined with metoprolol in patients with heart failure.
