Purpose: Critically ill patients with preserved or increased renal function have been shown to be at risk of underexposure to meropenem. Although many meropenem population pharmacokinetic (PK) models have been published, there is no large prospective population PK study with rich sampling focusing on patients most at risk of suboptimal pharmacokinetic/pharmacodynamic (PK/PD) target attainment. Therefore, the aim of the present study was to evaluate PK/PD target attainment and to perform a thorough covariate screening using population PK modelling of meropenem in septic patients with preserved or increased renal function.

Patients and Methods: A single-centre prospective observational PK study was performed in the intensive care unit (ICU) of the University Hospitals Leuven. Patients with severe sepsis or septic shock and treated with meropenem in the ICU were screened for inclusion. Patients were excluded if they received renal replacement therapy or had an estimated glomerular filtration rate according to the Chronic Kidney Disease Epidemiology collaboration equation $<70 \text{ mL/min/1.73m}^2$ on the day of PK sampling. Successful PK/PD target attainment was defined as an unbound meropenem trough concentration above 2 mg/L or 8 mg/L. Population PK modelling was performed with NONMEM7.4.

Results: In total, 58 patients were included, contributing 345 plasma samples over 70 dosing intervals. The 2 mg/L and 8 mg/L targets were successfully attained in 46% and 11% of all dosing intervals, respectively. A two-compartment population PK model with linear elimination and interindividual variability on clearance best described meropenem PK. The estimated creatinine clearance according to the Cockcroft-Gault equation was the only covariate retained during population PK analysis.

Conclusion: This study provided detailed insight into meropenem PK in critically ill patients with preserved or increased renal function. We observed poor PK/PD target attainment, for which renal function was the only significant covariate.

Trial Registration: This study is registered at ClinicalTrials.gov (NCT03560557).

Keywords: intensive care, PK/PD, exposure, dose optimization, augmented renal clearance

Introduction

Severe bacterial infections frequently lead to sepsis and septic shock, which are common causes of death in the intensive care unit (ICU). Worldwide, patients with sepsis reach unacceptably high mortality rates of 25% and even more in patients with septic shock.^{1,2} It is generally accepted that “early goal directed antimicrobial therapy”, referring to the initiation of adequate antimicrobial agents in the right dose as early as possible, significantly decreases mortality rates and has the

potential to avoid emerging resistance in patients with severe sepsis and septic shock.^{3,4} However, until control of the inflammatory reaction has been attained, antimicrobial pharmacokinetics (PK) are extremely altered due to pathophysiological disturbances associated with critical illness. Augmented renal clearance (ARC) and increased volume of distribution may lead to subtherapeutic antimicrobial exposure, resulting in therapeutic failure and induction of antimicrobial resistance.^{5–9}

Meropenem is a broad-spectrum beta-lactam antibiotic used to treat life-threatening infections in the ICU. It is commonly used in the empiric therapy of sepsis or complicated infections and in the targeted therapy of multi-drug-resistant gram-negative pathogens.¹⁰ Meropenem is a time-dependent bactericidal antibiotic. In critically ill patients, unbound concentrations exceeding 1- to 4-fold the minimal inhibitory concentration throughout the whole dosing interval ($100\% f_{T>1-4 \times MIC}$) are recommended for optimal bacterial killing and to avoid emergence of antimicrobial resistance.^{9,11} Several studies have shown that conventional meropenem dosing regimens may lead to unacceptable PK/pharmacodynamic (PK/PD) target attainment in critically ill patients. ARC, but also preserved renal function, has been identified as major causes for underexposure.^{9,12–15} This is not surprising as meropenem shows major renal clearance (approx. 70%).¹⁶ Alternative dosing strategies, such as extended or continuous infusion, have been suggested.¹⁷ Nevertheless, conventional dosing is still common as there is currently no consensus on meropenem dosing in critically ill patients and therapeutic drug monitoring for meropenem is still not implemented in most ICUs.^{18,19} Several population PK (population PK) models have been published in an attempt to describe and predict meropenem exposure in critically ill patients. Recently, Dhaese et al have shown that there is substantial variability in the predictive performance of these population PK models.¹⁷ This could be because these models were developed in rather small and selected populations (9–34 patients). Recently, a few population PK models have been developed in larger ICU populations, although these were based on data from retrospective studies^{20,21} or included mainly patients with impaired renal function.¹³

Therefore, the aim of the present study was to prospectively evaluate PK/PD target attainment in a larger study population with sepsis and preserved or increased renal function and to perform a thorough covariate screening using population PK modelling of meropenem.

Materials and Methods

Study Design and Setting

A prospective single-centre observational cohort study was carried out on the ICUs of a tertiary-care academic hospital (University Hospitals Leuven, Leuven, Belgium) between October 2013 and October 2017. The study was conducted in accordance with the Declaration of Helsinki, and the study protocol was approved by the Ethics Committee Research UZ/KU Leuven (S54511). Written informed consent was obtained from the patient or the closest relative before inclusion in this study. All adult patients admitted to the ICU, treated with meropenem and having severe sepsis or septic shock (as defined according to the definitions applicable at the time of the study; cf. [File S1](#))^{22,23} at the start of meropenem therapy were screened for inclusion. Exclusion criteria were pregnancy, do-not-resuscitate order, extracorporeal membrane oxygenation, renal replacement therapy, decreased renal function defined as an estimated glomerular filtration rate according to the Chronic Kidney Disease Epidemiology Collaboration equation ($eGFR_{CKD-EPI}$) <70 mL/min/1.73 m² on the day of PK sampling.

In the present study, ARC was defined as a measured urinary creatinine clearance by 24h urine collection ($mCrCl_{24h}$) ≥ 130 mL/min/1.73m², according to the consensus in the current literature.²⁴

Study Protocol

The study protocol has been previously published.²⁵ In short, blood samples were collected on an early day (day 2 ± 1) and/or a later day (day 5 ± 1) of meropenem therapy, depending on practical feasibility. Sampling was performed around one dosing interval at –15 minutes (pre-dose), 30 (at time of infusion stop), 120, and 240 minutes after the start of the infusion, and 15 minutes before the start of the next infusion (pre-dose). Meropenem was administered as an intermittent infusion and dosing was at the discretion of the treating physician. As reported previously, during the first year of the study, plasma samples were stored at -20°C until quantification.²⁵ However, new insights revealed significant degradation during long-term storage of meropenem at -20°C .^{26,27} Subsequently, from the beginning of the second year of the study on, all plasma samples were stored at -80°C within 24 hours after collection, until quantification within one year. For the plasma samples that were stored at -20°C for maximum one year, meropenem concentrations were corrected using

a validated degradation model.²⁸ Total meropenem concentrations were treated as unbound concentrations due to negligible plasma protein binding of meropenem (ie, 2%).¹⁶ Meropenem plasma concentrations were quantified using a validated ultra-performance liquid chromatography method coupled with tandem mass spectrometry, which has been described in detail elsewhere.²⁵

PK/PD Target Attainment

Based on current recommendations for therapeutic drug monitoring of meropenem in the ICU, PK/PD target attainment was defined as 100% $fT_{>MIC}$ ¹¹ and 100% $fT_{>4 \times MIC}$.⁹ The 100% $fT_{>MIC}$ and 100% $fT_{>4 \times MIC}$ are recommended for maximal bacterial killing¹¹ and optimal clinical outcome while avoiding emerging resistance⁹ with beta-lactam antibiotics in critically ill patients, respectively. As no exact minimal inhibitory concentration values were available, to calculate PK/PD target attainment, the minimal inhibitory concentration clinical breakpoint for susceptibility of Enterobacterales to meropenem (ie, 2 mg/L) – as recommended by the European Committee on Antimicrobial Susceptibility Testing – was used.²⁹ Thus, PK/PD target attainment was defined as unbound concentrations exceeding 2 mg/L or 8 mg/L throughout the whole dosing interval, corresponding to 100% $fT_{>MIC}$ and 100% $fT_{>4 \times MIC}$, respectively.

Population PK Modelling

Population PK analysis was performed using NONMEM (version 7.4; ICON Development Solutions, Gaithersburg, MD, USA), with a GNU Fortran 95 compiler and the Perl-speaks-NONMEM (PsN; version 4.7.0) toolkit on the interface software Pirana (version 2.9.7; Certara, Inc., Princeton, NJ, USA).

First-order conditional estimation with interaction and differential equation solver ADVAN 13 was used for parameter estimation. The precision of the parameter estimates was evaluated based on the root squared error. A base model was developed by evaluating different structural models with varying numbers of compartments (one, two and three compartments) and the presence or absence of interindividual and inter-occasion variability in the PK parameters. An occasion was defined as a dosing interval. Individual PK parameters were assumed to be ln-normally distributed using an exponential function. For example, the clearance (CL) parametrisation followed this equation:

$$CL_i = TVCL \times \exp(\eta_i) \text{ with } \eta_i \propto N(0, \omega^2) \quad (\text{Eq.1})$$

with CL_i the clearance of subject i , TVCL the typical population value of the clearance, η_i the individual subject's deviation from the typical value, and ω^2 is the variance of inter-subject variability. Allometric scaling was tested with exponents of 0.75 and 1 on CL and volume of distribution, respectively.

The base model (including the number of compartments) was selected by objective function value comparisons (difference ≥ 3.84 points; $P \leq 0.05$), the condition number (<1000), physiological plausibility and precision of parameter estimates, and goodness-of-fit plots. A final model, including covariate effects, was built via a two-way stepwise covariate modelling procedure (forward inclusion $\alpha=0.010$; backward elimination $\alpha=0.001$). The tested covariates were selected based on previously published (population) PK studies of meropenem and expert consensus, and included age, body weight, body mass index, ideal body weight, adjusted body weight, serum creatinine, estimated creatinine clearance according to the Cockcroft-Gault equation ($eCrCl_{CG}$), eGFR according to the Modification of Diet in Renal Disease equation, $eGFR_{CKD-EPI}$, $mCrCl_{24h}$, probability of ARC on the day of sampling according to the ARC predictor,³⁰ fluid balance, and Acute Physiology and Chronic Health Evaluation II, and Sequential Organ Failure Assessment scores.

The final model was evaluated using a prediction-corrected visual predictive check ($n = 1000$). Good predictive ability of the final model was defined as median values and 95% confidence intervals of the prediction-corrected observed data falling within the 95% prediction intervals of the model, which was illustrated using this prediction-corrected visual predictive check. Furthermore, bootstrapping was performed to obtain nonparametric estimates of uncertainty in parameter estimates ($n = 2000$ bootstraps).

The NONMEM control stream of the final population PK model is available in [File S2](#).

Statistical Analysis Not Related to Population PK Modelling

The results are expressed as median [interquartile range]. Differences in meropenem trough concentrations or PK/PD target attainment were evaluated using an unpaired Student's t -test or a Chi-square test, respectively. All analyses other than the population PK were performed in R (version 4.0.0, R Core Team, Vienna, Austria) in the

RStudio integrated development environment (version 1.3; RStudio, Inc., Boston, MA, USA) using the tidyverse³¹ collection of packages and ggplot2.³²

Results

Patient Characteristics

In total, 58 patients were included, contributing 345 plasma samples over 70 dosing intervals, as shown in the inclusion flow diagram ([Supplementary Figure 1](#)). The main clinical characteristics are shown in [Table 1](#). Sixty-nine percent of our cohort were male patients. Age and weight were 63 years [55; 68] and 70 kg [60; 79], respectively. The Acute Physiology and Chronic Health Evaluation II and Sequential Organ Failure Assessment scores on admission were 20 [16; 25] and 9 [7; 10], respectively. Most patients (83%) were sampled on an early day. Twelve patients were sampled on an early and a late day during meropenem treatment ([Table 1](#)). The $mCrCl_{24h}$ was 84 mL/min/1.73m² [64; 119] and 109 mL/min/1.73m² [75; 136] on early and late sampling days, respectively. Overall, the $mCrCl_{24h}$ was 88 [69; 128], and ARC was present on 16/66 (24.2%) dosing intervals for which $mCrCl_{24h}$ was available. On most sampling days (64%), patients received meropenem 1000 mg q8h. The remaining patients received meropenem 2000 mg q8h, except for two sampling days (500 mg q8h). All patients received meropenem as a short infusion over 30 minutes. The infection focus was mainly respiratory (72%). Forty-seven (81%) patients survived their ICU stay.

PK/PD Target Attainment

The median meropenem unbound trough concentration was 1.83 mg/L [0.73; 4.85]. Trough concentrations were 1.92 mg/L [0.82; 4.37] and 1.14 mg/L [0.58; 2.96] on early and late sampling days. There was no significant difference in trough concentrations between early vs late sampling days ($p = 0.88$). No concentrations were below the lower limit of quantification (0.09 mg/L). The 100% $fT_{>MIC}$ and 100% $fT_{>4 \times MIC}$ PK/PD targets – considering a minimal inhibitory concentration of 2 mg/L – were successfully attained on 46% and 11% of all sampling days, respectively ([Table 1](#)). Although there was a slight decrease in attainment of the 100% $fT_{>MIC}$ target, there was no significant difference in target attainment between early vs late sampling days ($p = 0.42$), as illustrated in [Figure 1](#).

Population Pharmacokinetic Modelling

A two-compartment population PK model with linear elimination best described the PK of meropenem. Interoccasion variability in PK could not be identified. IIV was identified on clearance (57.8% coefficient of variation [CV]), volume of the central compartment (57% CV), and volume of the peripheral compartment (74.4% CV). Allometric scaling was not retained since it did not improve the base model (goodness-of-fit plots of the base model are shown in [Supplementary Figure 2](#)). After performing stepwise covariate modelling, $eCrCl_{CG}$ was the only covariate withheld in our final model, explaining 18% of the IIV on CL. The $eCrCl_{CG}$ performed significantly better than any other covariate. Equation 2 shows how meropenem clearance of patient i increases with $eCrCl_{CG}$:

$$CL_i = 13.7 \frac{L}{h} \times \left(\frac{eCrCl_{CG}}{111.7 \text{ mL/min}} \right)^{0.725} \quad (\text{Eq.2})$$

Parameter estimates of the final model are shown in [Table 2](#). Goodness-of-fit plots showed that the final model adequately described the observed data ([Supplementary Figure 3](#)). A prediction-corrected visual predictive check showed the good predictive ability of our model, where the median values and the 95% confidence intervals of the prediction-corrected observed data fell within the 95% prediction intervals of the model ([Figure 2](#)). Median values of the nonparametric bootstrap replicates were in good agreement with point estimates ([Table 2](#)).

Discussion

In this study, we showed poor PK/PD target attainment of meropenem in critically ill patients with preserved or increased renal function. Solely renal function was retained as a significant predictor of meropenem exposure during population PK analysis.

Only half of the patients achieved the most conservative of both predefined PK/PD targets. Target attainment was equally low on early vs late sampling days, despite a slight increase in renal function. A previously published study investigating PK changes during meropenem therapy in septic patients also found no significant difference in target attainment and PK between early and late sampling days, despite increased renal function.³³ Interestingly, both in the latter and in the present study, there is a trend towards lower trough concentrations – and target

attainment – on the late sampling day. The effect of increased meropenem CL on the late sampling day might be relatively small compared to the already increased CL on the early sampling day, and/or it might be partially cancelled by decreased volume of distribution after the initial phase of sepsis.

We developed a two-compartment population PK model that was able to accurately predict meropenem plasma concentrations in patients with preserved or increased renal function. Previously, both one- and two-compartment models have been developed for meropenem in critically ill patients. Most one-compartment models have been developed in patients with prolonged

infusion^{17,20,34} and/or sparse sampling.²¹ Hence, it is not surprising that a two-compartmental model best fitted the PK data collected in the present study with rich sampling during intermittent infusion. Interestingly, it should be noted that a recent comparative study confirmed similar predictive performance of (one- and two-compartmental) population PK models developed in patients receiving continuous vs intermittent infusion.¹⁷

Renal function was found to be the only significant predictor of meropenem PK. This is consistent with the vast majority of previously published population PK models of meropenem in ICU patients.¹⁷ It has been reported that patients with preserved or increased renal function (ie,

Figure 1 Observed unbound meropenem plasma concentrations (mg/L) vs time relative to the start of the infusion (hours). Panel (A) represents the early sampling days, panel (B) represents the late sampling days. The dashed lines represent the 2 mg/L and 8 mg/L PK/PD target. The lines connect different observations within the same patient.

ARC) are most at risk of underexposure.^{35,36} This was the initial incentive for this study, ie, to focus only on patients with preserved or increased renal function. Recently, dosing simulations revealed that meropenem dosing according to the drug label is only sufficient for critically ill patients with an $eCrCl_{CG} < 60$ mL/min.¹³ Moreover, another simulation study showed that not only extended infusion but also higher meropenem doses were needed to achieve

a sufficiently high probability of target attainment when targeting 100% $fT_{>4 \times MIC}$ considering a minimal inhibitory concentration of 2 mg/L in critically ill patients with an $eGFR_{CKD-EPI} > 60$ mL/min.²¹ Notwithstanding, many population PK models included a significant proportion of patients with decreased renal function. To date, meropenem population PK modelling was mostly carried out in rather small¹⁷ or retrospective studies with sparse

Table 2 Population PK Model Parameter Estimates

Parameter	Estimate (%RSE) (95% CI) [%Shrinkage]	Bootstrap Median (95% CI)
Typical Values		
CL (L/h)	13.7 (7.4) (11.8–15.7)	13.6 (11.7–16.1)
V_c (L)	25.5 (8.5) (21.3–29.7)	24.8 (19.9–30.4)
V_p (L)	12.4 (15.8) (8.6–16.2)	12.7 (8.5–19.4)
Q (L/h)	8.1 (32.6) (2.9–13.3)	8.6 (3.5–15.7)
$eCrCl_{CG}$ on CL	0.64 (20.9) (0.37–0.90)	0.64 (0.34–0.90)
Interindividual variability		
IIV on CL (%CV)	57.8 (12.2) (44–71.6) [3]	56.8 (43–75.9)
IIV on V_c (%CV)	57 (16.8) (38.2–75.8) [14]	56.6 (31.3–78.9)
IIV on V_p (%CV)	74.4 (24.5) (38.6–110.1) [25]	77.2 (34.6–146.6)
Correlation between CL & V_c	0.185	0.178 (0.054–0.373)
Residual variability		
Additive residual variability (mg/L)	0.147 (45.6) (0.1–0.19) [16]	0.155 (0.002–0.782)
Proportional residual variability (%CV)	31.1 (17.2) (21.34–40.9) [16]	29.1 (21.2–39.4)

Notes: The model dOFV was 1655.702. 1831 out 2000 bootstrap runs (91.5%) were successful. The condition number was 99.74.

Figure 2 Prediction-corrected visual predictive check of the final model. The observed prediction-corrected meropenem concentrations are represented by circles. The black solid and dashed lines represent median and 2.5th and 97.5th percentile of the prediction-corrected observations, respectively. The shaded areas indicate 95% prediction-intervals of the median and 2.5th and 97.5th percentile of the simulated values.

sampling.^{20,21} The largest prospective meropenem population PK study to date only included a minority of patients with preserved renal function (32% had an $eCrCl_{CG} > 60$ mL/min).¹³ In the latter, only 11% of all patients showed ARC (defined as $eCrCl_{CG} \geq 130$ mL/min), whereas ARC was present during 24% of the dosing intervals in the present study. In the present study, overall median $mCrCl_{24h}$ was 88 mL/min/1.73m². This is much higher than renal function values reported in the abovementioned population PK studies. Hence, the present population PK model is a valuable addition to existing meropenem population PK models. The present population PK model can be used in future studies to evaluate dose optimization strategies for meropenem in critically ill patients with preserved or increased renal function.

In the present study, the median population estimated meropenem CL was 13.7 L/h, which is higher than in several of the previously developed population PK models.^{13,17,20,21,37} On the other hand, a few smaller prospective PK studies have also reported high meropenem CL values similar to the CL observed in the present study.^{35,38,39} Measured or estimated CrCl in these studies was similar to the $mCrCl_{24h}$ in the current study population.

Hence, it is not surprising that we found high meropenem CL values. This is a direct consequence of the exclusion criteria applied in the present study. For meropenem CL, despite the inclusion of renal function in the population PK model, IIV is still large. This is in accordance with findings from Dhaese et al.¹⁷ In their comparative study, they found that differences in renal function in the original dataset used to develop the population PK model do not fully explain the variability in their predictive performance. No other covariate mentioned to potentially influence meropenem PK (eg, Sequential Organ Failure Assessment score, Acute Physiology and Chronic Health Evaluation II score, age, body weight) has been identified consistently in population PK studies. Accordingly, we did not retain any of these covariates in our population PK analysis.

This study has several strengths. First, this is the largest prospective PK study with rich sampling in patients with preserved or increased renal function. This study allows a detailed description of meropenem PK in patients most at risk for underexposure and critical evaluation of previously published models. Second, $mCrCl_{24h}$ was collected in most patients (66/70 dosing intervals). The $mCrCl_{24h}$ is considered to be the pragmatic gold standard

in the ICU to monitor renal function.⁴⁰ Nonetheless, $eCrCl_{CG}$ was found to be the best predictor of the current model. This could be due to the fact that $mCrCl_{24h}$ was missing for eight dosing intervals, which were imputed with the median $mCrCl_{24h}$. A similar finding was observed in the population PK study of Dhaese et al, who retained $eCrCl_{CG}$ as significant predictor instead of $mCrCl_{8h}$.¹⁷

On the other hand, several limitations also need to be acknowledged. First, minimal inhibitory concentration values were not reported in the present study. Hence, we assessed PK/PD target attainment according to a worst case scenario, using the clinical minimal inhibitory concentration breakpoint for susceptibility of Enterobacterales to meropenem.²⁹ This breakpoint is consistent with the epidemiological cut-off (<http://www.eucast.org> (accessed on 24 March 2021)) and the previously reported MIC₉₀ (90% of pathogens have an equal or lower minimal inhibitory concentration) of *Pseudomonas aeruginosa*.¹³ Second, an external validation is lacking. A recent comparative study found substantial variability in the predictive performance of eight population PK models of meropenem.¹⁷ Nevertheless, awaiting external validation, this study clearly shows the urgent need for dose optimization in critically ill patients with preserved or increased renal function. Third, sample size was limited (ie, 58 patients), although our study represents the largest prospective population PK study of meropenem so far.

Conclusion

In conclusion, this study provided detailed insight into meropenem PK in critically ill patients with preserved or increased renal function. We observed poor PK/PD target attainment, which reflects the urgent need for dose optimization of meropenem in these patients. Thorough covariate screening using population PK modelling identified only renal function as a significant predictor of meropenem PK. External validation is desirable before implementing dose optimization strategies based on this population PK model.

Infection and Drug Resistance

Dovepress

Publish your work in this journal

Infection and Drug Resistance is an international, peer-reviewed open-access journal that focuses on the optimal treatment of infection (bacterial, fungal and viral) and the development and institution of preventive strategies to minimize the development and spread of resistance. The journal is specifically concerned with the epidemiology of

antibiotic resistance and the mechanisms of resistance development and diffusion in both hospitals and the community. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
