Abstract: Schizoaffective disorder is characterized by the presence of symptoms of both schizophrenia and a major mood disorder. The coexistence of these symptoms can be difficult to manage, and these patients are generally treated with antipsychotics as well as mood stabilizers and/or antidepressants. Additionally, no established treatment guidelines exist for this disorder. This review describes the combined results of two international, double-blind, placebo-controlled clinical studies of paliperidone extended-release (ER), an atypical antipsychotic recently approved in the US for the treatment of schizoaffective disorder. Subjects in these six-week trials were aged 18–65 years, had a diagnosis of schizoaffective disorder based on the Structured Clinical Interview for DSM-IV (Diagnostic and Statistical Manual of Mental Disorders, 4th Edition) Disorders, and were experiencing an acute exacerbation. The subjects from these studies had significant symptomatology as evidenced by a mean (standard deviation) baseline Positive and Negative Syndrome Scale total score of 92.8 (13.0). Based on Young Mania Rating Scale and/or a 21-item Hamilton Rating Scale for Depression score of $16 at baseline, 79.5% and 66.9% of subjects presented with prominent manic and depressive symptoms, respectively, and 46.4% presented with mixed symptoms. Approximately half (45%) of subjects were taking adjunctive mood stabilizers and/or antidepressants. Paliperidone ER was found to be effective in improving psychotic and mood symptoms in these subjects. Paliperidone ER was also effective as monotherapy or adjunctive to mood stabilizers and/or antidepressants for subjects with prominent manic, depressive, or mixed symptoms at baseline. No new tolerability signals were observed in this population. To the best of our awareness, these pooled data provide the largest data set of patients with schizoaffective disorder, and extend our knowledge of disease characteristics and treatment response.

Keywords: paliperidone extended-release, antipsychotic, schizoaffective disorder

Introduction

The term "schizoaffective", used to describe patients with concurrent schizophrenic and mood symptoms, was first introduced more than 75 years ago. Diagnosis of schizoaffective disorder requires that patients experience an uninterrupted period of illness with concurrent psychotic and mood symptoms. The psychotic symptoms must be present without any prominent mood symptoms for at least two weeks, yet mood episodes must represent a substantial portion of the total duration of illness. Patients with schizoaffective disorder are further classified as having the bipolar or depressive type (Diagnostic and Statistical Manual of Mental Disorders, 4th Edition [DSM-IV]). Epidemiologic data suggest that schizoaffective disorder is about one third as common as schizophrenia, with a lifetime prevalence of 0.3%, compared with 0.9% for schizophrenia, and such patients are regularly encountered in psychiatric
Two large, international, double-blind, placebo-controlled, randomized, six-week studies with paliperidone extended-release...
(ER) were conducted for schizoaffective disorder.\textsuperscript{29,30} Paliperidone ER is the first agent approved by the US Food and Drug Administration and several other countries (Australia, Brazil, New Zealand, and Philippines) to treat patients with schizoaffective disorder, both as monotherapy and as adjunctive therapy with mood stabilizers and/or antidepressants.\textsuperscript{31} In contrast with other antipsychotics, paliperidone ER undergoes limited hepatic metabolism and is therefore less likely to cause hepatically mediated drug–drug interactions in patients receiving multiple medications.\textsuperscript{32–34} This review of pooled data from the combined studies covers the largest data set of patients with schizoaffective disorder from randomized controlled trials to date, and provides insights into the characteristics and treatment responses of this understudied population.

**Description of the studies**

Subjects in these studies were aged 18–65 years, with a diagnosis of schizoaffective disorder based on the Structured Clinical Interview for DSM-IV Disorders (SCID). All were experiencing an acute exacerbation of illness as evidenced by a Positive and Negative Syndrome Scale (PANSS)\textsuperscript{35} total score $\geq 60$ and a score $\geq 4$ on at least two of the PANSS items for hostility, excitement, tension, uncooperativeness, and poor impulse control. Prominent mood symptoms were reflected in a score $\geq 16$ on the Young Mania Rating Scale (YMRS)\textsuperscript{36} and/or the 21-item Hamilton Rating Scale for Depression (HAM-D-21).\textsuperscript{37} In the first study, subjects received fixed dosages of paliperidone ER, ie, either the higher dosage (12 mg/day, with the option to reduce to 9 mg/day) or the lower dosage (6 mg/day, with the option to reduce to 3 mg/day).\textsuperscript{29} In the second study, paliperidone ER was flexibly dosed, beginning at a dosage of 6 mg/day, with a range of 3 to 12 mg/day.\textsuperscript{30} For both studies, any dosing changes had to occur within the first 15 days. Subjects receiving stable regimens of mood stabilizers and/or antidepressants were permitted to continue their ongoing treatment to allow the study of paliperidone ER either as monotherapy or as an adjunct to mood stabilizers and/or antidepressants.

Change in PANSS total score from baseline to endpoint was the primary outcome measure for both studies. Secondary efficacy measures were changes from baseline to endpoint for the Clinical Global Impressions of Severity for Schizoaffective Disorder (CGI-S-SCA),\textsuperscript{38} PANSS factor scores,\textsuperscript{39} a composite response (\geq30\% improvement in PANSS total score and Clinical Global Impressions of Change for Schizoaffective Disorder [CGI-C-SCA] of 1 or 2 [much or very much improved]), and the YMRS and HAM-D-21 scales. Safety assessments included adverse event reporting, clinical laboratory tests (including prolactin levels), and assessment of movement disorders with the Simpson-Angus Scale (SAS), Barnes Akathisia Scale (BAS), and Abnormal Involuntary Movement Scale (AIMS).\textsuperscript{40–42}

Randomization for both studies was stratified by center and by treatment with concomitant medications (with or without mood stabilizers and/or antidepressants). Data from the two schizoaffective studies were integrated (paliperidone ER versus placebo) for all statistical analyses. Efficacy was analyzed using the intent-to-treat analysis set, which included all randomized subjects who received \geq 1 dose of study medication and had a baseline and \geq 1 postbaseline PANSS assessment. The safety population included randomized subjects who received \geq 1 dose of study medication. For each continuous parameter, treatment group differences were analyzed using separate analysis-of-covariance (ANCOVA) models with treatment, protocol, country-within-protocol, concomitant medication stratum as fixed-effect design factors, and baseline score as a covariate. To assess consistency of treatment effect within each subgroup, separate ANCOVA models were fit. A Forest plot by subgroups was generated showing least-squares mean estimates and 95\% confidence intervals (CIs) for pairwise differences between paliperidone ER and placebo at week 6 last-observation-carried-forward (LOCF) endpoint. Change from baseline in efficacy measures (observed case) was also analyzed using a repeated-measures mixed-effects linear model. This model included baseline PANSS total score as a covariate; treatment, protocol, country-within-protocol, concomitant medication stratum, and time (scheduled assessment visits on day 4 and at weeks 1, 2, 3, 4, and 6) as factors; and the interaction between time and treatment. The correlation of the repeated measures is modeled with an unstructured covariance matrix. Between-group differences in percentage of subjects who met the composite response were evaluated using Fisher’s exact test. Effect sizes were calculated using Cohen’s $d$ methodology. Relative risks (RRs) and their corresponding 95\% CIs were calculated for adverse events with \geq5\% incidence for paliperidone ER or placebo. RR analyses were considered potentially significant ($P = 0.05$) when the 95\% CIs did not include 1. No adjustments were made for multiplicity.

**Population characteristics**

A total of 627 randomized subjects were in the pooled analysis (Figure 1). In the intent-to-treat analysis set ($n = 614$), 414 subjects received paliperidone ER and 200
received placebo. The mean (standard deviation [SD]) age of the combined population was 37.4 (9.9) years (Table 1). In contrast with the male-to-female ratio of patients with schizoaffective disorder in the literature, but typical of the ratio among subjects included in clinical studies, there were more male than female subjects. The majority (90.9%) of subjects had a chart diagnosis of schizoaffective disorder prior to screening, and more subjects were diagnosed with the bipolar type than the depressive type. The mean age at first schizoaffective disorder diagnosis was approximately six years later than the age at first psychiatric diagnosis, which was consistent with other observations that the diagnosis emerges over time. Subjects had received various other previous diagnoses, with schizophrenia being the most common. Nearly one third of subjects had attempted suicide; one half of this group of subjects had made two or more suicide attempts. Mean baseline scores for the P ANSS total, YMRS, and HAM-D-21 scales indicated that subjects had significant symptoms. Two hundred and seventy-five subjects (45%) were receiving adjunctive mood stabilizers and/or antidepressants at baseline and continued these medications during the study; 69% were taking a mood stabilizer, and 49% were taking an antidepressant. Valproic acid was the most frequently used mood stabilizer; the most frequently used antidepressants were escitalopram, sertraline, and venlafaxine (Table 2). Also, 14% of subjects in the total population were using medications for extrapyramidal symptoms, and 50% were using nonbenzodiazepine hypnotics and anxiolytics.

The studies were designed to include dosages from 3 to 12 mg/day, based on the recommended dose range for schizophrenia. The mean (SD) modal dosage of paliperidone ER in the combined studies was 8.6 (2.8) mg/day. Sixty-seven percent of subjects receiving paliperidone ER and 57% of those receiving placebo completed the study. The most common cause for discontinuation was lack of efficacy for 10% of the paliperidone ER subjects and 19% for the placebo subjects (Figure 1).

**Efficacy**

The PANS total score improved significantly more with paliperidone ER than with placebo from day 4 through to

and domain scores, were greater with paliperidone ER than with placebo (Table 3). Results using a repeated-measures linear model were consistent with those of the LOCF analysis (Table 3). Composite response rates were higher with paliperidone ER (50%) than with placebo (35%, $P < 0.001$, Figure 4).

**Paliperidone ER alone or adjunctive to mood stabilizers and/or antidepressants**

Approximately one half of the population was receiving mood stabilizers and/or antidepressants at baseline and continued these medications during the study, which allowed examination of the efficacy of paliperidone ER with or without mood stabilizers and/or antidepressants. Mean (SD) PANSS total scores at baseline were similar for subjects in both groups at 93.1 (13.0) for subjects receiving paliperidone ER as monotherapy and 93.5 (13.6) in those receiving paliperidone ER adjunctive to mood stabilizers and/or antidepressants. Improvement at the six-week endpoint was greater with paliperidone ER than with placebo in both groups (Figure 3).

Notes: The repeated-measures mixed-effects ANCOVA model included the baseline score as a fixed-effect covariate; treatment, concomitant medication stratum, country, study, country nested within study, and time (scheduled visit assessment) as fixed-effect (categoric) factors; and treatment by visit interaction. The correlation of the repeated measures is modeled with an unstructured covariance matrix. aThe LOCF analysis is based on an ANCOVA model with fixed effects for treatment, study, country nested within study, and the baseline value as a covariate. *P ≤ 0.001, palipidone ER vs placebo; **P < 0.01, palipidone ER vs placebo; ***P < 0.05, palipidone ER vs placebo.

Abbreviations: ANCOVA, analysis-of-covariance; CGI-S-SCA, Clinical Global Impressions-Severity-Schizoaffective Disorder; ER, extended-release; LS, least-squares; HAM-D-21, 21-item Hamilton Rating Scale for Depression; LOCF, last-observation-carried-forward; PANSS, Positive and Negative Syndrome Scale; SE, standard error; YMRS, Young Mania Rating Scale.

Figure 3 Adjusted mean differences and 95% CIs for PANSS total change scores at endpoint with palipidone ER versus placebo (intent-to-treat analysis set).

Notes: Analysis is based on an ANCOVA model with fixed effects for treatment, study, country nested within study, and the baseline value as a covariate. *P ≤ 0.001, palipidone ER vs placebo; **P < 0.05, palipidone ER vs placebo.

Abbreviations: CI, confidence interval; ER, extended-release; HAM-D-21, 21-item Hamilton Rating Scale for Depression; LS, least-squares; MS/ADs, mood stabilizers/antidepressants; PANSS, Positive and Negative Syndrome Scale; YMRS, Young Mania Rating Scale.
Subjects with prominent manic, depressive, or mixed symptoms

The size of the pooled population allowed for additional subgroup analyses based on the prominence of baseline affective symptoms (subjects with YMRS and/or HAM-D-21 score ≥ 16 at baseline). PANSS total scores improved significantly more with paliperidone ER than with placebo in each of these groups at endpoint (Figure 3).

Further analyses of these subgroups examined the effect of paliperidone ER on mood symptoms. Improvements in YMRS and HAM-D-21 were greater with paliperidone ER than with placebo, as measured by placebo-adjusted least-squares mean (95% CI) changes from baseline of −4.8 (−6.8, −2.9) and −3.8 (−5.5, −2.0), respectively. Both YMRS and HAM-D-21 scores improved with paliperidone ER as monotherapy or as adjunctive therapy with mood stabilizers and/or antidepressants (Figure 5).

Tolerability

The most frequent adverse events (≥5.0% in paliperidone ER subjects) among subjects receiving paliperidone ER versus placebo were headache (14.3% versus 14.9%), tremor (8.1% versus 3.5%), dizziness (6.7% versus 5.9%), insomnia (6.7% versus 6.9%), nausea (6.4% versus 5.9%), akathisia (5.5% versus 4.5%), hypertonia (5.5% versus 2.0%), dyspepsia (5.5% versus 2.5%), somnolence (5.2% versus 2.0%), and sedation (5.0% versus 3.5%). An analysis of RR found a greater risk of tremor with paliperidone ER than with placebo (RR = 2.34; 95% CI = 1.05, 5.18, Figure 6). Significance for increased risk (defined as the 95% CI not including 1) of the other adverse events was not observed.

The overall adverse event rate was higher in subjects who received paliperidone ER as adjunctive therapy to mood stabilizers and/or antidepressants (70.4%, paliperidone ER; 70.0%, placebo) than in those who received paliperidone ER as monotherapy (60.5%, paliperidone ER; 49.1%, placebo). An analysis of RR found a greater risk of tremor with paliperidone ER than with placebo (RR = 4.38; 95% CI = 1.04, 18.56) in the monotherapy group (Figure 6). Significance for increased risk of adverse events was not observed in the mood stabilizer and/or antidepressant group.

The percentage of discontinuations due to adverse events was similar for both the paliperidone ER- and the placebo-treated groups (each 7%) but was slightly higher in the group receiving paliperidone ER adjunctive to mood stabilizers and/or antidepressants (8.2%) than in the group receiving paliperidone ER as monotherapy (5.0%).
Adverse events of particular relevance with antipsychotic therapy are extrapyramidal symptoms, weight and metabolic changes, and prolactin elevation. Extrapyramidal symptoms were reported in 19.8% of subjects receiving paliperidone ER and in 10.9% of those receiving placebo. The severity of extrapyramidal symptoms as measured using the SAS, AIMS, and BAS was low (global score < 1) in both groups at baseline and endpoint.

At endpoint, mean (SD) changes in prolactin levels (ng/mL) were greater with paliperidone ER versus placebo for both males (12.6 [20.1] versus −3.6 [13.3]) and females (51.4 [62.1] versus −13.9 [32.4]). There were 9 (2.1%) subjects receiving paliperidone ER and one (0.5%) subject receiving placebo who experienced a potentially prolactin-related adverse event. The mean (SD) weight change was 1.0 (2.7) kg for paliperidone ER and 0.2 (2.1) kg for placebo. There were no clinically relevant differences in the lipid profile or fasting glucose levels for paliperidone ER compared with placebo.

Additionally, no clinically relevant differences were found in the incidence of extrapyramidal symptoms or in changes in mean weight, lipid profile, fasting glucose level, or prolactin level between subjects who received paliperidone ER as monotherapy and those who received paliperidone ER adjunctive to mood stabilizers and/or antidepressants (Table 4).

Figure 5 Adjusted mean differences and 95% confidence intervals for total YMRS and HAM-D-21 change scores at endpoint with paliperidone ER versus placebo in patients with manic or depressive symptoms at baseline (intent-to-treat analysis set).

Notes: Analysis is based on an ANCOVA model with fixed effects for treatment, study, country nested within study, and the baseline value as a covariate. *P ≤ 0.001, paliperidone ER versus placebo; †P ≤ 0.05, paliperidone ER versus placebo.

Discussion

To our awareness, this review covers the largest data set of patients with schizoaffective disorder, and provides additional knowledge to paliperidone ER. Although differential diagnosis across the psychosis and mood continuum can be challenging, over 90% of subjects were acutely ill at study entry. The mean age at first schizoaffective disorder diagnosis was approximately 37 years, with an average of six psychiatric hospitalizations per subject, and a previous suicide attempt reported in over 30% of subjects. These subjects were acutely ill at study entry. Interestingly, the mean age at first psychiatric diagnosis was approximately six years later than the age at first suicide attempt. The data presented here demonstrate that patients with schizoaffective disorder can be successfully treated with paliperidone ER. Although the mean modal dosage of paliperidone ER in these data was 8 mg/day, the recommended dosage for schizoaffective disorder is 6 mg/day. Additionally, although the lower-dosage group (3 to 6 mg/day) in the dose-response study was not superior to placebo with regard to PANSS total change compared with placebo in the two-dose group study, the majority of patients randomized to paliperidone ER in these studies were similar to those found in studies of paliperidone ER in schizophrenia. As expected, the potent D2 antagonism of paliperidone ER compared with other typical antipsychotics resulted in an elevation in serum prolactin levels and displayed high levels of concurrent psychotic, manic, and depressive symptoms. Notably, approximately one half of this population was receiving concomitant mood stabilizers and/or antidepressants at baseline. Treatment-emergent adverse events (including extrapyramidal symptom-related adverse events) and changes in weight and metabolic parameters were identified in these weight and metabolic parameters were associated with a significantly higher composite response rate. The data presented here demonstrate that patients with schizoaffective disorder can be successfully treated with paliperidone ER. Although the mean modal dosage of paliperidone ER in these data was 8 mg/day, the recommended dosage for schizoaffective disorder is 6 mg/day. Additionally, although the lower-dosage group (3 to 6 mg/day) in the dose-response study was not superior to placebo with regard to PANSS total change compared with placebo in the two-dose group study, the majority of patients randomized to paliperidone ER in these studies were similar to those found in studies of paliperidone ER in schizophrenia. As expected, the potent D2 antagonism of paliperidone ER compared with other typical antipsychotics resulted in an elevation in serum prolactin levels and displayed high levels of concurrent psychotic, manic, and depressive symptoms. Notably, approximately one half of this population was receiving concomitant mood stabilizers and/or antidepressants at baseline. Treatment-emergent adverse events (including extrapyramidal symptom-related adverse events) and changes in weight and metabolic parameters were identified in these weight and metabolic parameters were associated with a significantly higher composite response rate.
antidepressants,26–28 results suggesting that paliperidone ER is efficacious both as monotherapy and adjunctive to mood stabilizers and/or antidepressants may be particularly valuable to the clinician. With the exception of tremor, the tolerability of paliperidone ER was comparable when used as monotherapy or adjunctive to mood stabilizers and/or antidepressants. However, it must be noted that although randomization was stratified by mood stabilizer and/or antidepressant use, the study was not designed to compare monotherapy with adjunctive therapy or to compare the relative efficacy of various adjunctive combinations, and the benefits and risks of specific combinations of paliperidone ER and mood stabilizers and/or antidepressants have not been studied. Nonetheless, no unique tolerability issues were identified with paliperidone ER in this population. Because of its limited liability for hepatically mediated drug–drug interactions, paliperidone ER may be a useful option for patients who follow complex medication regimens.32–34

Several additional factors must be considered in the interpretation of these results. First, this study population may have been biased toward subjects experiencing manic symptoms because of the specified entry criteria. Nevertheless, in addition to the 80% of subjects who displayed prominent manic symptoms, 67% of subjects displayed prominent depressive symptoms at baseline. Moreover, subjects with prominent manic, depressive, or mixed symptoms at baseline had significant psychotic and mood symptom improvement with paliperidone ER compared with placebo. Finally, long-term maintenance treatment with paliperidone ER has not yet been studied in this population. However, such a trial is planned with paliperidone palmitate, the once-monthly injectable formulation of paliperidone.

Conclusion

Although schizoaffective disorder is commonly encountered in populations of patients with mental illness, this disorder has not been methodically studied, and no established guidelines exist for the management of these patients. Data pooled from two large, international, placebo-controlled, six-week studies with paliperidone ER are now available, demonstrating that acutely ill patients with schizoaffective disorder manifest high levels of psychotic, manic, and depressive symptoms at baseline. Patients who received paliperidone ER, either as monotherapy or adjunctive to mood stabilizers and/or antidepressants, experienced significant improvement in schizoaffective symptoms. Subjects with prominent manic, depressive, or mixed symptoms at baseline showed significant psychotic and mood symptom improvement with paliperidone ER compared with placebo. Additionally, no new tolerability signals were detected in this patient population. These data demonstrate the efficacy and tolerability of paliperidone ER as monotherapy or adjunctive to mood stabilizers and/or antidepressants in the acute treatment of schizoaffective disorder.

Neuropsychiatric Disease and Treatment

Publish your work in this journal

Neuropsychiatric Disease and Treatment is an international, peer-reviewed journal of clinical therapeutics and pharmacology focusing on concise rapid reporting of clinical or pre-clinical studies on a range of neuropsychiatric and neurological disorders. This journal is indexed on PubMed Central, the ‘PsycINFO’ database and CAS, and is the official journal of The International Neuropsychiatric Association (INA). The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit http://www.dovepress.com/testimonials.php to read real quotes from published authors.
