Abstract: Although tigecycline is widely used in clinical practice, its efficiency and optimal dosage regimens remain controversial. The purpose of this article was to help guide tigecycline dosing in different patient subpopulations through comparing the published population pharmacokinetic models of tigecycline, as well as summarizing and determining the potential covariates that markedly influence tigecycline pharmacokinetics. In this review, literature was systematically searched from the PubMed database from inception to March 2022. The articles focusing on population pharmacokinetics for tigecycline in healthy volunteers or patients were included; finally, a total of eight studies were included in this review. NONMEM methods were used in five studies to generate the population pharmacokinetic models. Tigecycline pharmacokinetics were mostly described by a two-compartment model in these included studies. Estimated clearance and volumes of distribution of tigecycline at steady state (V_{ss}) varied widely in different target patient populations, with a range of 7.5–23.1 L/h and 212.7–1087.7 L, respectively. Body-weight and creatinine clearance were the most important predictors of clearance in these studies, while other predictors include age, gender, bilirubin and aspartate aminotransferase. In conclusion, this review showed the large variability of tigecycline population pharmacokinetics, which can provide guide dosing in different target populations. For clinicians, the individual dosing adjustment should be based not only on the indication and pathogen susceptibility but also on the potential important predictors. However, more studies were needed to confirm the necessity of modified dosage regimens in different patient subpopulations.

Keywords: tigecycline, population pharmacokinetics, modelling, NONMEM

Introduction

Tigecycline, an antimicrobial agent of glycylycylcline class, is approved to treat complicated skin and skin structure infections, complicated intra-abdominal infections, and community-acquired pneumonia by the Food and Drug Administration in America since June 2005.¹ The primary mechanism of tigecycline is to bind to a helical region (H34) on the 30S subunit of bacterial ribosomes and inhibit bacterial protein translation.² Hence, tigecycline possesses high activities against gram-positive, almost all the gram-negative and anaerobic microorganisms.^{3,4} Due to its broad-spectrum antibacterial activities, tigecycline has been considered as one of the most important agents for treating complicated multi-drug resistant pathogen infections.

The recommended standard dose of tigecycline is a 100 mg starting dose, followed by 50 mg twice daily. Tigecycline has an extensive tissue distribution in the body, as its distribution volume ranges from 7 to 10 L/kg. Systemic clearance and the elimination half-life for tigecycline range from 0.2 to 0.3 L/h/kg and 37 to 67 hours, respectively.³ Tigecycline can highly combine with plasma proteins and exhibit atypical non-linear protein binding. AUC/MIC is considered as the most optimal parameter for pharmacokinetic/pharmacodynamic (PK/PD) to predict the efficacy of tigecycline.⁵ In vitro, it was suggested that tigecycline exhibits excellent activities against most Gram-positive and Gram-negative pathogens. Yaghoubi et al reported that tigecycline showed a prolonged postantibiotic effect and displayed a time-dependent

bactericidal activity in a 3 mg/kg dose.⁶ Compared with tetracycline, tigecycline was more effective for the *Enterococcus faecalis* ATCC47077 (a tetracycline-susceptible pathogen).⁷ However, the efficacy of standard dose tigecycline in clinical application is still controversial. Several studies recently reported that the recommended standard dose of tigecycline exerted insufficient antimicrobial activities in different target patient populations.^{8,9} A higher dosage of tigecycline (100 mg twice daily) was related to better outcomes in HAP patients.¹⁰ A higher dosage of tigecycline could also achieve a better cure rate and be associated with better outcomes in critically ill patients with multidrug-resistant bacteria infection.¹¹ Therefore, optimizing the dosage of tigecycline to improve its efficacy in different target patient population is still need to be clarified.

Recently, the FDA issued a black boxed warning and illustrated that treatment with tigecycline increased the risk of death in FDA-approved and non-approved diseases.¹² Several clinical studies have shown that the use of tigecycline was related to higher mortality than other comparator antibiotics.^{13–15} A meta-analysis also demonstrated that compared with the control groups, the clinical response and mortality in the tigecycline-treated group showed no difference. Tigecycline could not induce better outcomes when compared with other antibiotics in treating complicated multi-drug-resistant pathogen infections, and the mortality in the tigecycline-treated group was even higher than others. Therefore, Ni et al concluded that the use of tigecycline might not be the best choice.¹⁶ However, the potential reason for this higher mortality is still unknown. Freire et al attributed the increased risk of death to suboptimal tigecycline dosing.¹⁷ Therefore, the FDA advised that tigecycline should be used only in situations when other treating methods are not suitable.^{10,11} However, due to its strong antimicrobial activities and lack of other effective antimicrobials, tigecycline is still used in complicated multi-drug-resistant pathogen infections as the antibiotic of last resort.

Population pharmacokinetics provided clinicians a useful method to investigate pharmacokinetic variability in different patient subpopulations and to determine covariates that influence drug pharmacokinetics. To decrease the potential adverse reactions of the tigecycline and maintain its efficacy, the population pharmacokinetics of tigecycline has been studied in different target patient populations, including intensively sampled volunteers and sparsely sampled patients. This review aims to comprehensively summarize all population pharmacokinetics analyses of tigecycline (from inception to March 2022). In this review, we systemically compared the population pharmacokinetic models of tigecycline and explored the potential covariates that might influence the pharmacokinetic models.

Materials and Methods

Search Strategy

Literature collected for the review was systematically searched from the PubMed database from inception to March 2022. The following search terms were employed: tigecycline AND (population pharmacokinetic OR pharmacokinetic analysis OR pharmacokinetic model OR NONMEM OR non-linear mixed effect model). All articles were reviewed and double-checked.

Inclusion and Exclusion Criteria

The articles focusing on population pharmacokinetic for tigecycline in healthy or patients could be included as it met the following criteria: (1) Study population in literatures should be human; (2) The administration of tigecycline should be intravenous injection; (3) The analysis method used in the study should be population pharmacokinetic analysis; (4) Original data were used; and (5) The language of the study should be published in English.

Excluded criteria used in this review were as follows: (1) The articles were in vitro or animal studies; (2) The articles were meta-analysis, methodology, and review articles; and (3) The population PK modeling approach was not used.

Data Extraction

All the literature that met the inclusion criteria was collected and the relevant information was extracted. For example, the first authors, the publication year, the country of the study, the characteristics of the population (including the number of patients (male/female), type of the special population, age, body-weight, creatinine clearance, and the levels of albumin), study clinical protocol (including the type of study (retrospective/prospective), the dosage of tigecycline

supplementation, the time point, the frequency of sampling, the quantification methods of tigecycline, lower limit of quantification, the instrument used, the population pharmacokinetic modeling methods and techniques (including software used in the studies, the methods of evaluation, and covariate selection strategies), as well as the PopPK models and covariates analysis (including the final formula of PopPK structural and the values of related parameters, the covariates were tested and preserved).

Results

Literature Collection

A total of 169 potentially relevant articles were obtained when the search strategies were performed, of which 30 remained after scanning abstract and title. After the full-text assessment, eight of them met the inclusion criteria and were included in this review (Figure 1).^{18–25} The characteristics of the relevant eight articles are summarized in Table 1. The patients included in this review were from five countries. Specifically, the patients in two studies were from China, the patients in two studies were from the USA, while the patients in one study were from Poland, Germany, and Spain, respectively. The year of publication range from 2007 to 2022. The number of patients included in these eight studies varied widely, and ranged from 11 patients (Broeker et al) to 410 patients (Rubino et al). Furthermore, the type of population recruited in these studies included healthy volunteers, the patients with intra-abdominal infections, the patients with community or hospital-acquired pneumonia, the patients with sepsis or septic shock, the patients with complicated intra-abdominal or skin and skin structure infections, and the patients with cirrhosis.

Study Designs and Analysis Methods

These studies collected in the present review contain five prospective studies (Broeker et al, Agnieszka et al, Xie et al, Zhou et al, and Bastida et al) and three retrospective studies (Rubino et al, Van Wart et al and Van Wart et al). Although the recommended standard dose of tigecycline is a 100 mg starting dose, followed by 50 mg twice daily; however, the dosage of tigecycline in these studies included in the review varied. The tigecycline administration route in five of the studies was by an intravenous infusion in standard dosage (100 mg loading, 50 mg q12h) or lower (50 mg loading, 25 mg

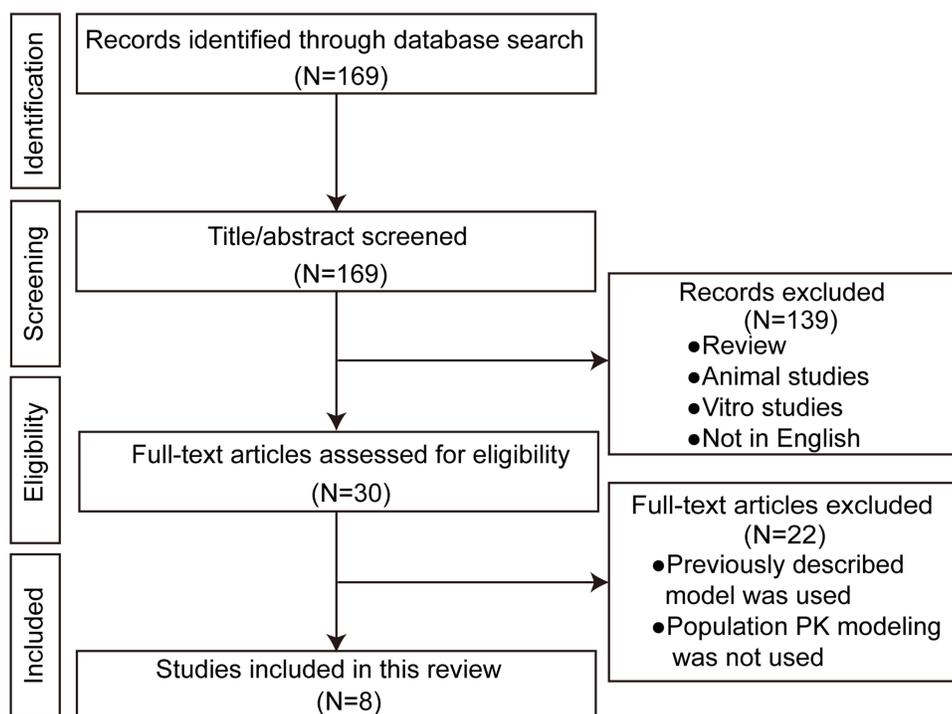

Figure 1 The selection process of the studies included in the systematic review.

Table 1 Summary of Patients' Demographics for All Population-Pharmacokinetic Studies Included in This Review

Study	Publication Year	Sample Size	Country	Population Characteristics					
				Patient Group	Sex (M/F)	Age (Year)	Weight (kg)	CLCR (mL/min)	Albumin (g/dl)
Broeker et al ²³	2018	11	Germany	Intra-abdominal infections with continuous veno-venous hemodialysis (n = 8) or hemodiafiltration (n = 3)	10/1	69 (37–81)	80 (68–104)	NR	2.8 (2.1–3.1)
Agnieszka et al ²⁴	2018	37	Poland	Sepsis or septic shock	26/11	61 (25–79)	80 (50–129)	NR	2.2 (1.5–3.6)
Xie et al ¹⁹	2017	10	China	Critically ill patients with severe infections	6/4	64 (36.5–73)	69.1 (59.7–70.8)	NR	2.8 (2.7–2.9)
Rubino et al ²²	2010	410	USA	Community or hospital-acquired pneumonia	250/160	56.0 (18.0–92.0)	74.0 (33.8–140)	75.7 (18.4–247) (mL/min/1.73m ²)	3.02 (1.20–5.30)
Van Wart et al ²¹	2007	174	USA	Healthy volunteers	149/25	35 (18–84)	76 (50–112)	NR	NR
Van Wart et al ²⁰	2006	146	USA	Complicated intra-abdominal or skin and skin structure infections	103/43	45.7 (18–82)	84.3 (47–227)	91.9 (24.2–278)	NR

Note: ^aMean ± SD.

Abbreviations: NR, not reported; M, male; F, female; CLCR, creatinine clearance.

q12h), and the tigecycline in one study conducted by Van Wart et al was administered by intravenous infusion in a single (12.5–300 mg) or multiple (25–100 mg, q12h) dosages. The only exception was conducted by Agnieszka et al who showed that the tigecycline was administered by intravenous infusion in higher dosage (200 mg loading, 100 mg q12h).²⁴ Besides, in Bastida's study, the dosage of tigecycline administration was not provided.²⁵ The time of samples collection in patients in these eight studies varied widely, for example, in Broeker's study, arterial blood samples were collected as follows: 0 (before the start of infusion), after the end of infusion (1, 1.25, 1.5, 1.75, 2, 4, 6, 8, and 12 h), while Zhou et al reported that the blood samples were obtained before the ninth dose of tigecycline and at 0, 3, and 8 h after the end of infusion.^{18,23} To quantify tigecycline concentrations in these samples, the high-performance liquid chromatography and liquid chromatography method with tandem mass spectrometer detection systems were used in these studies. The general characteristics of the clinical protocols for studies are summarized in Table 2.

Population Pharmacokinetic Analysis

As shown in Table 3, NONMEM methods were used in five of these studies to analyze data and generate the population pharmacokinetic models.^{20,21,23–25} Phoenix NLME, ADAPT, and R software were also used in the study of Zhou et al, Rubino et al, and Xie et al, respectively.^{18,19,22} Bootstrapping analysis, an internal evaluation method was used in five studies, external evaluations were used in two studies, and one study reported no information on the validations. The best way for modeling population pharmacokinetics of tigecycline was the two-compartmental model in seven analyses; however, three-compartment models were found to be more suitable to describe the subjects obtained single or multiple doses of tigecycline in the study of Van Wart et al²⁰

Several covariates were tested in the models including age, sex, race, body-weight, etc in different subpopulations (Table 3). In our review, the model evaluation in these studies was conducted through basic internal approaches such as goodness of fit, and advanced internal approaches such as bootstrap and visual predictive check. Age was tested as a covariate in all the studies included in our review, and only one study showed that age could affect tigecycline clearance.¹⁸ The influence of sex as a covariate on tigecycline clearance was tested in five studies; however, it was only included in the final model in one study.²⁰ Body-weight is also one of the significant covariates on tigecycline clearance, and six of the studies tested it. In two of these studies, the tigecycline clearance is increased with increasing body-weight.^{18,20} However, no significant effect of body-weight has been found in other four studies. Furthermore, although the covariate creatinine clearance was only included in five population pharmacokinetic models, two studies showed a significant effect of creatinine clearance on tigecycline.^{20,22} Interestingly, Bastida et al recently reported that Model for End-stage Liver Disease (MELD) score and total serum proteins significantly influenced the clearance of tigecycline in critically ill patients with decompensated cirrhosis and severe infections.²⁵ In addition, other significant covariates on tigecycline clearance included BMI, body surface area, bilirubin, and aspartate aminotransferase.

Clearance and Volume of Distribution

In the final population pharmacokinetic models of these studies included in the review, the clearance of tigecycline ranged from 7.50 to 23.1 L/h. The clearance of tigecycline and between-subjects variability of the included studies is presented in Figure 2. High tigecycline clearance was observed in the following subpopulations: patients with hospital-acquired pneumonia in China, patients with sepsis or septic shock in Poland, patients with community or hospital-acquired pneumonia in the USA, and patients with intra-abdominal infections receiving either continuous veno-venous hemodialysis or hemodiafiltration in Germany. However, the clearance of tigecycline in the lower spectrum was also observed in one study in critically ill patients with severe infections in China.¹⁹

In the studies included in the review, the estimated volumes of distribution varied widely. When detecting the total volume of distribution, the lowest was 212.7 L, which was estimated in patients with intra-abdominal infections receiving either continuous veno-venous hemodialysis or hemodiafiltration in the study of Broeker et al²³ Among the estimated total volume of distribution (V_{ss}), the two highest were 1087.7 L and 759 L in healthy volunteers administering as multiple doses and patients with complicated intra-abdominal or skin and skin structure infections in the studies of Van Wart et al and Van Wart et al, respectively^{20,21} (Table 4).

Table 2 Summary of the Clinical Protocols for Studies Included in This Review

Study	Study Type	Dose	Samples' Time	Assay	LLQ
Broeker et al ²³	Prospective	100 mg (50 mg, q12h)	0 (before the start of infusion) and 1, 1.25, 1.5, 1.75, 2, 4, 6, 8, 12 h (after the end of infusion)	Ultrafiltration and high-performance liquid chromatography (HPLC)-UV	50 ng/mL
Agnieszka et al ²⁴	Prospective	200 mg (100 mg, q12h)	0.5, 2, 4, 8 and 12 h after each infusion	High-performance liquid chromatography	20 ng/mL
Xie et al ¹⁹	Prospective	100 mg (50 mg, q12h)	0 (before the seventh dose), 0.5, 1, 2, 3, 4, 6, 8, and 12 h (after the seventh dose)	Liquid chromatography-tandem mass spectrometry	5 ng/mL
Rubino et al ²²	Retrospective	100 mg (50 mg, q12h)	1. 0 h (before the first dose) 2. On any day on or after day 3 (after a minimum of 6 tigecycline doses): 0 h, within 10 min before the end of the infusion, within 1 min after the end of the infusion. 3. On any day on or after day 3 (after a minimum of 6 tigecycline doses), 3 and 6 h from the start of the infusion.	Liquid chromatography-tandem mass spectrometry	10 ng/mL
Van Wart et al ²¹	Retrospective	Signal dose (12.5–300 mg); Multiple doses (25–100 mg, q12h)	Single dose: (pre-dose, 0.5, 1, 1.5, 2, 3, 4, 4.5, 5, 6, 7, 8, 10, 12, 16, 24, 36, 48, 60, 72, and 96 h) Multiple doses: (pre-dose, 0.5, 1, 1.5, 2, 3, 4, 6, 8, and 12 h)	High-performance liquid chromatography-UV; Liquid chromatography methods with tandem mass spectrometer detection (LC/MS/MS)	25 ng/mL; 10 ng/mL
Van Wart et al ²⁰	Retrospective	100 mg (50 mg, q12h); 50 mg (25 mg, q12h)	Prior to dosing, at the end of infusion (either 0.5 h or 1 h), and at 3 h and 6 h after the start of infusion on the day before or the day of discharge from the study unit.	Liquid chromatography method with tandem mass spectrometer detection	10 ng/mL
Zhou et al ¹⁸	Prospective	100 mg (50 mg, q12h)	Before the 9th dose of tigecycline and at 0, 3, and 8 h after the end of infusion.	A two-dimensional liquid chromatographic system, which contains two parts: the first separation system (LC1) and second separation system (LC2).	35 ng/mL
Bastida et al ²⁵	Prospective	NR	30 min before drug administration (pre-dose), and 1, 2, 5 and 8–12 h after drug administration	Liquid chromatography-tandem mass spectrometry (UPLC-MS/MS) method	10 ng/mL

Abbreviations: NR, not reported; LLQ, lower limit of quantification.

Table 3 Population Pharmacokinetic Modeling Methods, Tested and Retained Covariates by the Studies Included in the Review

Study	Compartments	Software	Covariates Tested	Covariates Included in Final Model	Model Evaluation
Broeker et al ²³	Two-compartment model	NONMEM (Version 7)	Age, sex, bilirubin, creatinine concentration, creatinine clearance	Bilirubin	Goodness of fit and visual predictive check
Agnieszka et al ²⁴	Two-compartment model	NONMEM (Version 7)	Age, sex, weight, height, application of ECMO and CRRT, dialysis volume, ultrafiltration speed, extravascular lung water index, cardiac output, sequential organ failure assessment score, and procalcitonin concentration	Not found	Bootstrap and visual predictive check
Xie et al ¹⁹	Two-compartment model	Pmetrics package for R	Age, sex, height, body weight, body mass index, body surface area, creatinine concentration, creatinine clearance, albumin, and Acute Physiology and Chronic Health Evaluation II scores	Body mass index	Goodness of fit and visual predictive check
Rubino et al ²²	Two-compartment model	ADAPT	Age, sex, race, height, weight, bmi, ideal body weight, albumin, creatinine clearance, Acute Physiology and Chronic Health Evaluation II scores, nursing home residence, cerebrovascular disease, alcohol abuse, congestive heart failure, chronic obstructive pulmonary disease, current or previous smoking, diabetes, fine score, liver disease, neoplastic disease, renal disease, ventilator-associated pneumonia	Body surface area, creatinine clearance	Bootstrap
Van Wart et al ²¹	Three-compartment model and two-compartment model	NONMEM (Version 5)	Age, weight, gender, race, alkaline phosphatase, alanine aminotransferase, aspartate aminotransferase, bilirubin, creatinine clearance, plasma albumin, hematocrit, hemoglobin, and red blood cell count	Weight, creatinine clearance, gender	Goodness of fit
Van Wart et al ²⁰	Two-compartment model	NONMEM (Version 5)	NR	NR	Goodness of fit
Zhou et al ¹⁸	Two-compartment model	Phoenix NLMETM (Version 8.1)	Age, gender, body weight, alanine aminotransferase, aspartate aminotransferase, creatinine concentration, total bilirubin, direct bilirubin, albumin	Age, weight, creatinine concentration, aspartate aminotransferase	Bootstrap and visual predictive check
Bastida et al ²⁵	Two-compartment model	NONMEM (Version 7.4)	Age, body mass index, bilirubin, aspartate aminotransferase, creatinine clearance, and Body weight	MELD score and total serum proteins	Goodness-of-fit and predictive check

Abbreviations: NR, not reported; NONMEM, nonlinear mixed-effects modeling.

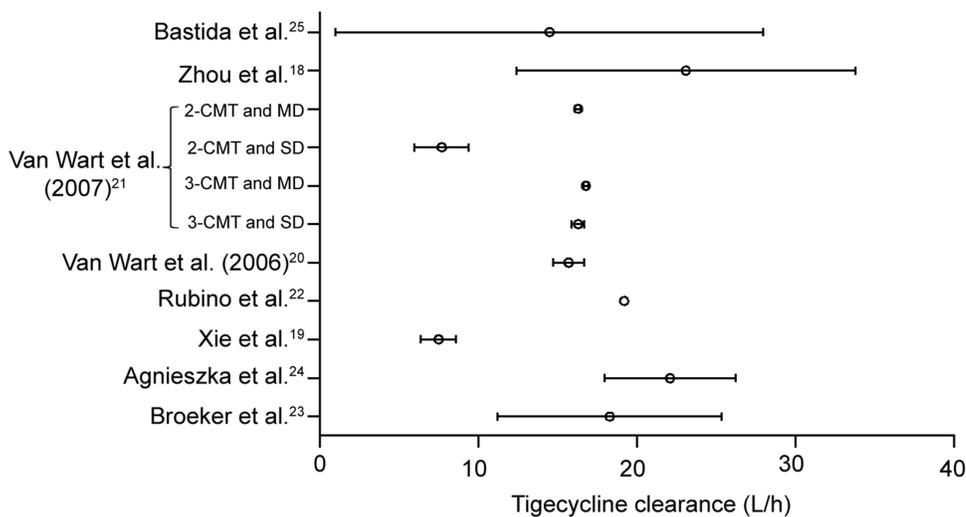

Figure 2 Tigecycline clearance and between-subjects variability of the included studies.

Discussion

Tigecycline, a crucial antibiotic, has been widely used as one of the agents for the treatment of complicated multi-drug-resistant pathogen infections. In clinical studies, the dosage of tigecycline should be carefully adjusted. The recommended standard dose of tigecycline is a 100 mg loading dose, followed by 50 mg twice daily; however, it is widely defined that the recommended dosing regimen is insufficient to treat MDR bacteria infections.⁶ Meanwhile, the adverse drug reactions of tigecycline also need to be carefully monitored.²⁶ Thus, numerous studies on tigecycline PK have been conducted and several population pharmacokinetic models have also been investigated since 2006 to ascertain the appropriate dosing in different target patient populations. To the best of our knowledge, this is the first review to summarize the literature knowledge on population pharmacokinetics of tigecycline.

The present review included eight different population pharmacokinetic analyses, which were conducted in four countries from 2006 to 2022. NONMEM is one of the softwares widely used in population pharmacokinetic modeling.²⁷ In the studies included in this review, NONMEM was used in five of the studies to identify relevant covariates and optimize the dosage of tigecycline in the respective subpopulation and almost all the studies showed that tigecycline PK with two-compartment models were more precise and adequate. The trends of PK estimates (clearance and volumes of distribution) between different target patient populations were not observed. The estimated clearance and volumes of distribution (V_1) of tigecycline varied widely in different target patient populations, with a range of 7.5–23.1 L/h and 23.9–162 L, respectively. However, in view of the difference between respective subpopulations, the study designs, the sample sizes, sampling time, and methods of covariates modeling, the interpretation of such ranges should be cautious and more investigation is required.

Most of the studies collected in the present review were conducted as prospective studies in special subpopulations, including critically ill patients with intra-abdominal infections, sepsis or septic shock, critically ill patients with severe infections and hospital-acquired pneumonia, as well as critically ill patients with decompensated cirrhosis and severe infections. Furthermore, according to the purpose of these studies, many aimed at investigating the relationships between tigecycline treatment and the clinical response as well as optimizing tigecycline dosage in the respective subpopulation. Insufficient sample size and representativity of samples might be limitations for these studies; therefore, the capability to evaluate parameters and detect significant covariates might be confined. Besides, the studies include in this review mostly measured the levels of tigecycline in plasma, which may not necessarily reflect concentrations at the target site. Stepwise covariates selection was the most commonly reported method. A large of different covariates were evaluated and age, sex, body-weight as well as creatinine clearance were identified as the most significant covariates in these studies.

Table 4 A Summary of Final Models, Fixed and Random Effect Models Described in the Included Studies

Reference	CL (L/h)			V1 (L)		V2		BSV			RV

Abbreviations: NR, not reported; CL, clearance; V₁, volume of distribution of the central compartment; V₂, volume of distribution of the peripheral compartment; BSV, between-subject variability; RV, residual variability; BSA, body surface area; CrCL, creatinine clearance; CLCrj, creatinine clearance (mL/min) of the jth patient; WTKGj, weight (kg) of the jth patient; WT, body weight; CMT, compartment; AST, aspartate aminotransferase.

With regard to the covariates, the age of the patients was tested as a covariate in all of the studies included in our review, and only one study showed that the age was associated with the PK parameters of tigecycline in patients (age range: 18–89 years) with HAP. Besides, the influence of age on the tigecycline has also been demonstrated in previous studies. Muralidharan et al reported that there were no significant differences in tigecycline pharmacokinetic parameters in different age groups (age: 18–50 vs 65–75 vs >75 years) in healthy subjects.²⁸ However, higher potential adverse events would be observed in older age groups (age range: >65 years).²⁹ Meanwhile, Liu et al also found that elderly patients (age range: 77.09 ± 15.11 years) were more prone to developing hypofibrinogenemia after the administration of tigecycline.³⁰ The reason for the differences among these studies may be due to the different health status and age distribution of the subjects selected in these studies. In clinical practice, tigecycline is usually used to treat life-threatening infections in elderly patients. This might also be explained by decreased liver blood flow, the changed metabolism of drug binding, and distribution with advanced age.

The associations between sex and tigecycline PK parameters were investigated in five studies. In Van Wart et al's study, the clearance of tigecycline was significantly related to sex in patients with complicated intra-abdominal or skin and skin structure infections and they found that males had a higher clearance of tigecycline as compared to females.²⁰ It is well known that tigecycline is extensively distributed to the bone, and bone mass in males was significantly higher than in females; therefore, higher bone mass in males may influence the redistribution of tigecycline. Consistently, the AUC_{0-24} in young women was approximately 21% higher than that in young men after a single dose of tigecycline exposure.²⁸ Interestingly, in the recent study, Fan et al also reported that females had a higher risk due to their greater accumulation of tigecycline than males.³¹ However, they did not observe a difference in another study in healthy volunteers.²⁸ Meanwhile, no correlation with sex was found in the other four studies included in this review. The potential reason for these contradictory results may be due to insufficient sample sizes and the diversity of patients.

The effects of body-weight as a covariate in patients on the pharmacokinetic parameters of tigecycline have been studied. Zhou et al reported that the weight of the patients with hospital-acquired pneumonia was related to the increased central volume of distribution and tigecycline clearance.¹⁸ Van Wart et al observed that the clearance of tigecycline in patients with cIAI or cSSSI was significantly influenced by body-weight.²⁰ Consistent with these studies, Xie et al also found that a larger BMI was associated with increased clearance of tigecycline in critically ill patients, while the final model was not provided and no obese subjects with PK data available for inclusion in their analysis.¹⁹ Furthermore, Rubino et al demonstrated that the body surface area was one of the significant predictors of interindividual variability on clearance.²² In contrast, no significant difference was obtained in another four studies. Meanwhile, the study of Pai et al reported that there was no difference in the clearance and volume of distribution between the obese and normal-weight healthy adults.³² Therefore, the importance of body-weight, body size, and BMI in the pharmacokinetics of tigecycline still needs to be investigated.

The parameters associated with liver functions, such as MELD score, bilirubin, aspartate aminotransferase, alkaline phosphatase, and/or alanine aminotransferase were also considered as covariates in some studies. In one study, the impact of bilirubin on tigecycline clearance was demonstrated.²³ Another study also recognized bilirubin as a crucial covariate, even though it was not included in the final model.²⁰ In addition, in Zhou et al's study, they tested the association between total bilirubin, direct bilirubin, and tigecycline clearance, while no significant differences were detected.¹⁸ However, they observed that the levels of aspartate aminotransferase, but not alkaline phosphatase and alanine aminotransferase were associated with decreased clearance in patients. Recently, the effects of liver functions on the pharmacokinetics of tigecycline were also investigated. Alraish et al found that compared with the patients with normal liver functions, the levels of tigecycline in plasma were remarkably higher in patients with severe liver failure.³³ In Van Wart et al study, there was no association between parameters associated with liver functions (bilirubin, aspartate aminotransferase, alkaline phosphatase and/or alanine aminotransferase) and the pharmacokinetics of tigecycline.²⁰ However, due to the complication of liver functions, which might be influenced by many factors. The effects of liver functions parameters on the pharmacokinetics of tigecycline still need to investigate with a larger sampling.

The renal function such as creatinine clearance and/or serum creatinine concentration also influenced the pharmacokinetic parameters of tigecycline in patients. Therefore, in some studies, these renal function indexes were also analyzed as covariates. In one study, creatinine concentrations were found to be able to influence tigecycline clearance.¹⁸

Moreover, another two studies found a close correlation between creatinine clearance and tigecycline clearance.^{20,22} Contrastly, Xie et al reported that there was no significant association between creatinine clearance, serum creatinine concentration and tigecycline clearance.¹⁹ Korth-Bradley et al also reported that tigecycline requires no dosage adjustment in patients with renal impairment.³⁴ In clinical practice, tigecycline clearance is usually calculated to change dosage recommendations, which is based on the body-height and serum creatinine concentration. Therefore, compared with serum creatinine concentration, creatinine clearance is a more reliable renal function index and importantly associated with tigecycline clearance. Therefore, when analyzing the tigecycline PK, it is important to detect the renal function, especially creatinine clearance.

Conclusion

In conclusion, this review included eight studies, which to develop special population pharmacokinetic models on tigecycline in different patient subpopulations including healthy volunteers or patients. Two-compartment models were mostly used to describe tigecycline population pharmacokinetics. The covariates reported in the studies included in this review varied widely in special subpopulations. Body-weight, and creatinine clearance were the most important predictors of clearance in these studies. However, other factors, such as metabolism, drug–drug interactions, and genetic polymorphisms might also influence the tigecycline PK considerably. Therefore, a more stringent sampling strategy and a larger sample size were needed to assess these factors efficiently. In addition, more accurate descriptions of the pharmacokinetic models are needed in the previously reported models and the future models.

Drug Design, Development and Therapy

Dovepress

Publish your work in this journal

Drug Design, Development and Therapy is an international, peer-reviewed open-access journal that spans the spectrum of drug design and development through to clinical applications. Clinical outcomes, patient safety, and programs for the development and effective, safe, and sustained use of medicines are a feature of the journal, which has also been accepted for indexing on PubMed Central. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
