**Background and Aims:** Patients affected by moderate-to-severe Ulcerative Colitis (UC) demand a challenging management. Small molecules, administrated as oral agents, have the ambition of overcoming the limitations of the biologic agents (ie, parenteral administration, rapidity of action, primary and secondary non-responsiveness). Beyond tofacitinib, a pan-Janus kinase (JAK) inhibitor already approved for the treatment of moderate-to-severe UC, novel more selective molecules like filgotinib are being currently evaluated in randomized clinical trials. We aimed to review the current evidence on filgotinib, a JAK-1 preferential inhibitor, in the treatment of UC and its place in therapy in the current scenario.

**Methods:** PubMed and EMBASE were searched to identify relevant studies: those investigating the efficacy and safety of filgotinib in the treatment of UC patients were included in this narrative review.

**Results:** The current preliminary data have shown that filgotinib is safe and effective in inducing clinical endoscopic response in both biologic-naïve and biologic-experienced patients with moderate-to-severe UC, also with high inflammatory burden at baseline. In the SELECTION trial, one case of pulmonary embolism occurred with filgotinib 200 mg induction, and three venous thrombosis cases were observed in the placebo maintenance/LTE; the incidence of herpes zoster was  $\leq 1\%$  in all UC treated patients. Filgotinib represents an appealing treatment option for its high selectiveness, route of administration and rapidity of action; cost-effectiveness studies and head-to-head trials are needed to better define its place in therapy.

**Keywords:** ulcerative colitis, filgotinib, Janus kinase inhibitors, efficacy, safety

## Introduction

Ulcerative colitis (UC) is a chronic, relapsing-remitting disorder affecting the colon and rectum characterized by mucosal and submucosal inflammation.<sup>1</sup> The pathogenesis of UC, despite not fully understood yet, is multifactorial and immune-mediated.<sup>1</sup> The progressive behavior of UC can potentially lead to disability and long-term complications such as dysplasia and cancer development, hospitalization and irreversible bowel damage eventually requiring proctocolectomy.<sup>2,3</sup>

As recommended by the Selecting Therapeutic Targets in IBD (STRIDE II), the reduction of these late complications represents the major endpoint and the backbone of medical treatment.<sup>4</sup>

In the very last years, the progress in the knowledge of pathological mechanisms together with the advancing biotechnologies have led to an increasingly rapid advent of novel biologics and small molecules available for the treatment of moderate-to-severe UC. In particular, since the introduction of anti-tumor necrosis factor alpha biologics (anti-TNF $\alpha$ ) (ie, infliximab, adalimumab, golimumab), anti-integrins (vedolizumab) and, more recently, of anti-interleukins (ustekinumab), the natural history of the disease has started to change. Increasing rates of corticosteroid-free remission, mucosal healing, deep remission, and an ameliorated quality of life of UC patients have become

possible.<sup>5-7</sup> Nevertheless, the treatment with biologics implicates various limitations, such as the primary non-responsiveness, a rather limited efficacy, the eventual secondary loss of response, and the risk of immunogenicity. Moreover, biologics have a parental administration, either intravenous or sub-cutaneous, which can impair their tolerance. Small molecules, administrated as oral agents, have the ambition of overcoming such limitations. Initially, tofacitinib, a Janus kinase (JAK) inhibitor, was the first small molecule drug approved by international regulatory authorities for the treatment moderate-to-severe UC.<sup>8</sup> Indeed, the cellular transduction pathway activated by JAK, intracellular tyrosine kinases, is involved in the pathogenesis of UC,<sup>9,10</sup> and its pharmacological inhibition has been demonstrated as an effective treatment for UC.<sup>8</sup> Filgotinib is an oral JAK1 preferential inhibitor, that has been evaluated in several randomized controlled trials (RCTs) for both rheumatological disorders (ie, psoriatic arthritis, ankylosing spondylitis)<sup>11-13</sup> and IBD, and finally approved in patients affected by rheumatoid arthritis and moderately to severely active UC. In 2016 the randomized, double-blind, placebo-controlled Phase 2 study, the FITZROY study provided the first evidences on the efficacy and safety of filgotinib for the treatment of active moderate-to-severe Crohn's disease (CD).<sup>14</sup> Specifically, in the treatment arm the clinical remission, defined as Crohn's Disease Activity Index (CDAI) less than 150 at week 10, was achieved by a significantly greater proportion of CD patients as compared with placebo (47% vs 23%, respectively,  $p=0.0077$ ).<sup>14</sup> Furthermore, filgotinib was superior to placebo as concerns improvements in quality of life, endoscopic response, remission, and deep remission in CD patients.<sup>14</sup>

In this clinical scenario of a constantly growing therapeutic armamentarium, due to the lack of studies of direct comparisons, drug positioning remains a clinical challenge for dedicated physicians with a focus on IBD.

In this review, we aim to examine and summarize the current evidence and the latest advances on filgotinib as a therapeutic agent for UC.

## Pharmacology

Small molecules are organic compounds characterized by a low molecular weight (<900 Da); they are mostly administered orally, and can pass through cell membranes reaching intracellular targets and regulating cellular transduction.<sup>15</sup> JAK inhibitors (JAKi) belong to this pharmacological class, being non-immunogenetic, rapidly absorbed and with short half-lives of a few hours.<sup>16</sup>

As concerns the rationale of inhibiting the JAK-STAT pathway, these cellular kinases are crucial in mediating the signaling of inflammatory cytokine.<sup>9,10</sup> JAK proteins, intracellular cytoplasmic tyrosine kinases, are divided into four subtypes: JAK1, JAK2, JAK3 and TYK2,<sup>17</sup> every JAK isoform exhibits binding preferences for different cytokines' receptors.<sup>17</sup> They are constitutively associated with intracellular domains of type I and/or type II cytokine receptors, once the extracellular ligand binds the receptor, JAKs activate in pairs via phosphorylation and downstream activate STAT transcription factors<sup>18,19</sup> (Figure 1). Finally, cellular growth, differentiation, migration, and survival, especially of the T lymphocytes, are regulated by this pathway.<sup>18,19</sup> Since every JAK subtype is associated with different cytokine receptors, its inhibition simultaneously modulates multiple effects.

Filgotinib is an orally, once daily administered JAKi, selectively blocking JAK1 and, in a lower degree, JAK2 with a greater potency as compared with JAK3 and TYK2.<sup>20</sup> A 28 to 30-fold higher selectivity in inhibiting JAK1 over JAK2 has been observed in human whole-blood assays.<sup>20</sup> The absorption of filgotinib is rapid and reaches the median peak plasma concentration 2 to 3 hours after administration.<sup>21</sup>

Importantly, the concentrations of filgotinib are not influenced by food or proton pump inhibitors' coadministration.<sup>20-22</sup> With respect to its metabolism, that occurs independently from CYP450, filgotinib is metabolized by carboxylesterases with the production of an active metabolite. The mean half-life of filgotinib is 7 hours, with a terminal elimination half-life of its active metabolite of 21 to 27 hours, after administration in single dose.<sup>21</sup> The contribution to the clinical activity is given both by the parent molecule and the active metabolite, and the maximum pharmacodynamic effects are achieved for the dosage of 200 mg filgotinib daily.<sup>21</sup> Filgotinib and its active metabolite are mainly eliminated in the urine (80-85%), but a small amount is eliminated throughout the intestine in the feces (15%).<sup>18</sup> The pharmacokinetics of filgotinib is affected by renal impairment only in advanced stages (estimated creatinine clearance [CrCl] from 30 to 60 mL/min, or CrCl from 15 to 30 mL/min): in these patients a lower dose (ie, 100 mg/day) is recommended.<sup>18,21</sup>

Furthermore, no clinically significant differences were observed in patients treated with filgotinib depending on age, gender, race or bodyweight.<sup>18,21</sup> Lastly, filgotinib and its active metabolite do not interact with uridine 5'-diphospho-

**Figure 1** JAK-STAT pathway in the signaling of inflammatory cytokines. JAK proteins are intracellular cytoplasmic tyrosine kinases constitutively associated with intracellular domains of type I and/or type II cytokine receptors; every JAK isoform exhibits binding preferences for different cytokines receptors. Once the extracellular ligand binds the receptor, JAKs activate in pairs via phosphorylation and downstream activate STAT transcription factors. This pathway regulates cellular growth, differentiation, migration, and survival, especially of the T lymphocytes. Created by Biorender.com.

glucuronosyltransferases, do not inhibit key drug transporters, and showed a lack of relevant pharmacokinetic interactions with drugs that are substrates of CYP3A4 (ie, midazolam, levonorgestrel/ethinyl estradiol) exhibiting a low liability for drug–drug interactions.<sup>23,24</sup>

Strictly linked to its mechanism of action, the most common adverse events (AEs) associated with filgotinib include upper respiratory infections, nasopharyngitis, urinary tract infections, nausea, headache, and occasional diarrhea. These reported AEs are generally not serious. Safety data of special interest (ie, incidence of herpes zoster and cardiovascular events) are discussed in details below.

Table 1 resumes the pharmacokinetic and pharmacodynamic features of filgotinib.

**Table 1** Pharmacokinetic and Pharmacodynamic Features of Filgotinib

Feature	Details	Note
Selectivity	Selective blockade of JAK1; JAK1 > JAK2 > JAK3	Filgotinib inhibits JAK1 with a greater potency as compared with JAK3 and TYK2 <sup>19</sup>
Administration	Oral, as single dose of 100* or 200* mg	Can be administered with or without food without affecting concentrations
Median peak plasma concentration	2 to 3 hours	Rapid absorption
Half-life	Parental molecule = 6 to 7 hours Active metabolite = 21 to 27 hours	Allows both single and repeated dose
Metabolism	Carboxylesterase 2 and carboxylesterase 1	CYP450-independent, relevant for drug-drug interactions
Excretion	Urinary = 85% Fecal = 15%	
Dose adjustment	No dose adjustment for CrCl > 60 mL/min	Filgotinib 100 mg per day if CrCl < 60 mL/min
Immunogenicity	None	Further advantage over biologics

**Note:** \*The two currently approved dosages.

**Abbreviations:** JAK, Janus kinases; CYP450, cytochromes P450; CrCl, creatinine clearance.

## Efficacy

The phase 2b/3, double-blind, randomised, placebo-controlled trial (the SELECTION trial), including two induction studies and one maintenance study, assessed the efficacy and safety of filgotinib in patients with moderately to severely active UC.<sup>25</sup> The treatment arms for both biologic-naïve (induction study A) and biologic-experienced (induction study B) patients, randomly assigned, were filgotinib 200 mg, filgotinib 100 mg, and placebo.<sup>25</sup> The primary endpoint of this trial was clinical remission at week 10, defined as Mayo endoscopic subscore  $\leq 1$ , rectal bleeding subscore = 0, and  $\geq 1$ -point decrease in stool frequency subscore from baseline to achieve a subscore  $\leq 1$ .<sup>25</sup>

Indeed, significantly higher rates of clinical remission at week 10 was achieved by both biologic-naïve and biologic-experienced patients given filgotinib 200 mg compared with placebo (26.1% vs 15.3%, 95% CI 2.1–19.5;  $p=0.0157$  and 11.5% vs 4.2%, 95% CI 1.6–12.8;  $p=0.0103$ , respectively).<sup>25</sup> As concerns the maintenance study phase, 37.2% of patients in the filgotinib 200 mg group remained in clinical remission at week 58, compared with 11.2% of patients in the placebo group (95% CI 16.0–35.9;  $p<0.0001$ ).<sup>25</sup> Clinical remission did not significantly differ between filgotinib 100 mg and placebo at week 10, but was significant at week 58 (23.8% vs 13.5%, 95% CI 0.0–20.7;  $p=0.0420$ ).<sup>25</sup> Remarkably, the efficacy of filgotinib 200 mg on clinical remission compared with placebo at week 58 was consistent across all the subgroups of patients (ie, biologic-naïve, biologic-experienced, anti-TNF $\alpha$  failure, vedolizumab failure, and both TNF antagonist and vedolizumab) both at week 10 and 58.<sup>25</sup> The investigated secondary endpoints in the induction studies were Mayo Clinic Score remission (a total of 2 or less and no single subscore higher than 1), endoscopic remission (defined as Mayo endoscopic subscore of 0), histologic remission (based on Geboes Scale), at week 10 and at week 58, whereas in the maintenance study, 6-months corticosteroid-free clinical remission and sustained clinical remission at week 58 were also assessed.<sup>25</sup> In details, endoscopic remission at week 10 was achieved by 12.2% of biologic-naïve patients given filgotinib 200 mg vs 3.6% of patients in the placebo group (95% CI 2.9–14.3;  $p=0.0047$ ) and by 3.4% of biologic-experienced patients given filgotinib 200 mg vs 2.1% of patients in the placebo group (95% CI 2.5–5.1;  $p=0.42$ ).<sup>25</sup> Furthermore, histologic remission at week 10 was achieved in a significantly higher proportion of biologic-naïve patients (35.1% vs 16.1%, 95% CI 9.9–28.2;  $p<0.0001$ ) and of biologic-experienced patients given filgotinib 200 mg (19.8 vs 8.5%, 95% CI 4.2–18.6;  $p=0.0019$ ) as compared to patients in the placebo group.<sup>25</sup> As concerns longer term endpoints, it was observed that at week 58 a significantly greater amount of patients receiving filgotinib 200 mg achieved all the secondary endpoints than those who received placebo.<sup>25</sup>

Recently, data of the interim analysis of the ongoing long-term extension (LTE) SELECTIONLTE trial have shown that filgotinib was effective in maintaining long-term improvements in UC with respect to symptoms' control and health-related quality of life (HRQoL).<sup>26</sup>

Moreover, in the sub-analysis of the SELECTION and SELECTIONLTE studies it has been reported that re-treating with filgotinib 200 mg patients with a disease worsening was beneficial: at LTE week 12, over 75% of patients had a clinical response and over 40% of patients were in clinical remission (based on partial Mayo score).<sup>27</sup>

Finally, the recently presented post-hoc analysis from the SELECTION trial, evaluating clinical, biological, health-related quality of life (HRQoL) remission and endoscopic improvements as a combined endpoint in UC patients treated with filgotinib 200 mg compared with placebo, reported that this combined endpoint was achieved by 17.6% vs 4.41% of the patients ( $p<0.001$ ) by week 10 in the biologic-naïve induction cohort, and by 22.1% vs 7.14% of the patients ( $p=0.002$ ) by week 58 in the maintenance cohort.<sup>28</sup> During maintenance a lower proportion of minimal clinically important difference (MCID) decline, assessed thorough EQ5D utility, and visual analogue scale, was experienced by those patients achieving the combined endpoint.<sup>28</sup>

Among the several sub-analyses available, the assessment of Work Productivity and Activity Impairment (WPAI) during the SELECTION trial demonstrated that a significant improvement of patients' general quality of life and work-related outcomes was achieved in the treatment arms with filgotinib 200 mg in comparison with placebo both in the induction and maintenance phases.<sup>29</sup>

Finally, filgotinib has been confirmed to be efficacious in inducing and maintaining clinical remission regardless of age, including UC patients aged  $>60$  years.<sup>30</sup>

## Safety

As concerns the safety profile of JAKi on IBD and other immune-mediated diseases patients, according to a recent meta-analysis that included also seven studies on filgotinib, the estimated global incidence rate of serious infection was 3.36 per 100 patient-years, and the estimated incidence of herpes zoster infection was 2.11 per 100 patient-years (>42,000 patients included in the analysis).<sup>31</sup> Furthermore, the authors reported an incidence rate of non-melanoma skin cancer (NMSC) of 0.51 per 100 patient-years (one study on filgotinib included, overall 26,334 patients exposed to JAKi), and an incidence rate of deep vein thrombosis and pulmonary embolism of 0.31 per 100 patient-years years (three studies on filgotinib included, overall 24,128 patients exposed to JAKi).<sup>31</sup>

Regarding the safety of filgotinib in UC, in the induction studies of the SELECTION trial, treatment-emergent adverse events were observed in similar proportion in the placebo, in the filgotinib 100 mg, and in the filgotinib 200 mg arms.<sup>25</sup> serious adverse events were reported in 4.7%, 5.0% and 4.3% of the patients, respectively.<sup>25</sup> In deeper details, no deaths occurred during the induction studies with filgotinib in UC patients and the main adverse events of interest were infections (82/562, 14.6% in filgotinib 100 mg; 92/507, 18.1% in filgotinib 200 mg).<sup>25</sup> Among these, 6 patients in the 100 mg treatment arm and 3 patients in the 200 mg treatment arms experienced a serious infection.<sup>25</sup> One case of pulmonary embolism occurred with filgotinib 200 mg induction and three venous thrombosis cases were observed in the placebo maintenance/LTE; the incidence of herpes zoster was  $\leq 1\%$  in all UC treated patients.<sup>21</sup> Adverse events, mostly mild or moderate in severity, in the maintenance study were comparably reported for both treated and untreated patients.<sup>25</sup>

Of note, in the LTE study safety events were comparable to those above reported and no new safety signals have been added.<sup>26</sup> Similarly, upon restarting therapy with filgotinib, safety was equivalent to aforementioned data and no new safety signals were classified.<sup>27</sup>

Nevertheless, attention should be paid to FDA warning regarding the increased risk of major adverse cardiovascular events, malignancy, thrombosis and mortality with all JAKi, including filgotinib. FDA recommends that clinicians find a balance between the benefits and risks for individual patients before starting or continuing treatment with JAKi, particularly among patients at higher risk of venous and arterial thrombosis (eg, current or past smokers, those who develop a malignancy, those with cardiovascular risk factors), as does EMA recommending additional monitoring in patients treated with filgotinib.<sup>32,33</sup>

Incidences of malignancies, non-melanoma skin cancer and major adverse cardiovascular events have been found to be slightly increased in patients aged  $\geq 60$  years compared with other age groups.<sup>30</sup>

Adult males with potential reproductive interest are another population who warrant attention due to findings observed in the male reproductive system of both dogs and rats' models, including dose-dependent impairment of spermatogenesis with reported cessation of sperm production, loss of spermatids, and seminiferous atrophy.<sup>34,35</sup> However, data on animals are reassuring since the histopathological findings were fully or partially reversible. Furthermore, the ongoing trials on rheumatoid arthritis and IBD male patients addressing testicular safety (NCT03926195 and NCT03201445) have confirmed the safety of filgotinib in the recent ad interim analysis.

Finally, safety data on the use of filgotinib in UC patients undergoing or scheduled for surgery with respect to suspension timing and possible post-operative complications are missing.

## Conclusion and Future Perspectives

This review illustrates the current evidence on efficacy and safety of filgotinib in the treatment of UC. Filgotinib is a second-generation JAKi, orally administered with a rapid mechanism of action. What emerges from our review is that, despite the lack of long-term data, the evidence on safety and efficacy of filgotinib is extremely encouraging.<sup>25–27</sup> In particular, as observed in the SELECTION trial, both clinical remission, endoscopic remission, and histologic remission were achieved in the treatment arm with filgotinib 200 mg.<sup>25</sup> These endpoints are particularly valuable in the treat-to-target era, where their achievement is increasingly being linked to the reduction of long-term complications. With respect to safety, the findings in UC patients were consistent to those observed for rheumatoid arthritis, and herpes zoster infections and serious infections occurred at low rates in all treatment groups,<sup>25</sup> differently from safety data reported for pan-JAKi.

A concern on an increased risk for venous thromboembolism for all agents in the JAK class exists, however, the available evidence on filgotinib is reassuring and risk minimization measures in clinical practice are manageable. Regarding testicular toxicity, ongoing trials will evaluate reproductive safety in adult males.

Treatment scenarios for moderate-to-severe UC are rapidly evolving toward more selective and safer drugs, with possibly higher rapidity of action, and filgotinib appears as an optimal candidate for providing fast clinical benefits, improving the quality of life of our patients with a safer profile as compared to several biologic agents. Filgotinib might additionally find place in the treatment of hospitalized patients with acute severe UC in analogy with tofacitinib, that, according to recent retrospective data, has been demonstrated to be an effective induction option in this life-threatening condition.<sup>36</sup>

The precise disease phenotype that might upmost respond to filgotinib is yet to be defined, surely a concomitant arthropathy and/or the failure to anti-TNF appear to be possible clinical criteria as well as steroid-dependency or in alternative to azathioprine. Wider data are needed to define the use of filgotinib in case of recent oncological history and in case of fragile or elderly patients. In addition, the shorter half-life of filgotinib in comparison to biologic agents might represent an advantage when a rapid drug elimination is needed (ie, for a scheduled surgery).

A further open issue regards the sequence of therapies. The most recent data derived from a Bayesian network meta-analysis in patients with moderate-to-severe UC have shown the superiority of upadacitinib in terms of both efficacy and safety compared with other therapies including filgotinib.<sup>37</sup> However, filgotinib followed upadacitinib in almost all sub-analyses.<sup>37</sup> Specifically designed head-to-head trials comparing the different molecules will clarify this matter.

Additional relevant aspects to consider are the costs of a long-term therapy with filgotinib. Indeed, in the treatment of rheumatoid arthritis, for each patient the average price per year is valued at £10.508 based on the list price.<sup>38</sup> As concerns UC, the exact costs for the annual treatment are still unknown, and cost-effectiveness studies are needed to support the prescription of filgotinib eventually above the different available biologic and non-biologic agents, keeping in mind that small molecules could also reduce the costs related to the scheduled visits for drug infusions and the necessity for a specialized nurse.

The current preliminary data have shown that filgotinib is safe and effective in inducing clinical and endoscopic response and remission in both biologic-naïve and biologic-experienced patients with moderate-to-severe UC, also with high inflammatory burden at baseline.<sup>25–27</sup> As far as we are concerned, filgotinib represents an appealing treatment option for its high selectiveness, route of administration and rapidity of action, pending its approval by regulatory authorities and availability on the market.

## Clinical and Experimental Gastroenterology

Dovepress

### Publish your work in this journal

Clinical and Experimental Gastroenterology is an international, peer-reviewed, open access, online journal publishing original research, reports, editorials, reviews and commentaries on all aspects of gastroenterology in the clinic and laboratory. This journal is indexed on American Chemical Society's Chemical Abstracts Service (CAS). The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
