Purpose: To describe a case of hypotony maculopathy following anti-VEGF intravitreal injection (IVI) in a patient with pseudoxanthoma elasticum (PE).

Methods: Clinical case report.

Results: A 52-year-old male complained of right eye (OD) vision loss 2 days after an uncomplicated anti-VEGF IVI for the treatment of choroidal neovascularization secondary to angioid streaks. Relevant medical history included PE, pathologic myopia, and a previous pars plana vitrectomy (PPV) due to a retinal detachment. OD best-corrected visual acuity (BCVA) dropped from 6/12 to 6/18 after the IVI. Intraocular pressure (IOP) was 3 mmHg and chorioretinal folds were evident in the posterior pole. Topical dexamethasone and atropine were prescribed, and full recovery was noticed after 3 days. Four months later, the patient developed a new episode of vision loss after another IVI. His BCVA was counting fingers, IOP was 2mmHg, and more noticeable chorioretinal folds were found. This time, an open scleral wound at the injection site was evident and a scleral suture was necessary. Once again, the patient recovered well.

Conclusion: Hypotony maculopathy following intravitreal injection is a rare condition. However, the described patient presented several conditions which could be related with poor scleral wound closure: intrinsic scleral fragility due to myopia and pseudoxanthoma elasticum; repeated IVI procedures; and absence of vitreous in the posterior segment due to prior vitrectomy. Despite the good outcome, hypotony maculopathy may be a sight-threatening condition, and special attention is necessary for specific patients with risk factors.

Keywords: hypotony maculopathy, intravitreal injection, anti-VEGF, pseudoxanthoma elasticum, angioid streaks

Introduction

Pseudoxanthoma elasticum (PE) is an autosomal recessive disease linked to a mutation in the ABCC6 gene. It causes fragmentation and calcification of the elastic fibers, generating dermatological, vascular, and ophthalmological malformations. The deterioration of the Bruch membrane's elastic fibers creates angioid streaks, which can develop choroidal neovascularization (CNV).¹

Anti-VEGF intravitreal injection (IVI) is commonly used to treat retinal conditions as CNV or diabetic macular edema. Despite being a safe procedure, several IVI are usually necessary to improve or preserve best-corrected visual acuity (BCVA) increasing the risk of adverse effects.

Hypotony maculopathy has been described as the eye globe low pressure that leads to anatomical and functional changes. The most common cause is glaucoma filtering surgery.² Despite the previous descriptions of wound leaks due to IVI,^{3,4} the relation with hypotony maculopathy is not usual. We aim to report a case of a hypotony maculopathy following an anti-VEGF intravitreal injection.

Materials and Methods

Description of a clinical case of hypotony maculopathy following anti-VEGF IVI in a patient with pseudoxanthoma elasticum and CNV secondary to angioid streaks.

Written informed consent for publication of this clinical case report was obtained from the patient. Institutional approval was required to publish the case details.

Results

A 52-years-old male presented visual acuity loss of his right eye (OD) 2 days after an uncomplicated ranibizumab IVI with a 30G needle. The past medical history included PE, high myopia, and OD pars plana vitrectomy due to retinal detachment. He was being treated with monthly ranibizumab due to choroidal neovascularization secondary to angioid streaks, with 78 previous injections in the OD. At presentation, his BCVA was 6/18 and the intraocular pressure (IOP) was 3 mmHg. Slit-lamp examination of the anterior segment was unremarkable. Fundoscopy and OCT-scans revealed posterior pole chorioretinal folds (Figure 1A). Altogether, the low intraocular pressure and fundoscopic findings led to the diagnosis of hypotony maculopathy. Topical dexamethasone and atropine were prescribed to improve ciliary body function. The IOP normalized within 3 days with a recovery of visual acuity and resolution of the chorioretinal folds. Four months later, a new OD anti-VEGF IVI with a 30G needle was performed in the inferolateral quadrant and the patient reported decreased visual acuity in the day following the injection. BCVA was counting fingers and IOP was 2 mmHg. Chorioretinal folds in the posterior pole were present, even more prominently this time (Figure 1B). Slit-lamp examination revealed an open scleral wound at the injection site. The wound was sutured with 10–0 monofilament and topical dexamethasone and atropine were prescribed. The patient recovered well (Figure 1C and D) and presented BCVA of 6/12 and an IOP of 12mmHg.

Figure 1 (A) Macular time-domain optical coherence tomography linear scan demonstrated several chorioretinal folds (arrows) in the posterior pole after an intravitreal injection (IVI). (B) Four months later, a new IVI was performed and the fundoscopic examination revealed large chorioretinal folds with marked ocular deformation. (C) After the treatment, macular time-domain optical coherence tomography linear scan and (D) fundoscopic examination showed the resolution of the previously seen chorioretinal folds.

Discussion

Despite being considered a safe procedure, IVI may damage the sclera, leading to some degree of scleral dehiscence.⁵ Prior cases of wound leak following IVI have been described. However, hypotony maculopathy has not been generally linked to the procedure, particularly with no evidence of wound leak, as described in the first episode of this clinical case. However, our patient presented special conditions that may have promoted the situation.

As so, the scleral thickness is thinner in older and myopic patients.^{6,7} Also, PE has been linked to “blue sclera”, a condition associated with a decreased scleral thickness,⁸ probably in the sequence of the fragmentation of the scleral elastic fibers. These were intrinsic characteristics of the patient.

Similarly, several IVI were given to the patient, which have been associated in the literature with localized scleral thinning in the site of the procedure.⁹ This finding may be caused by the scleral scar formation and hydration promoted by the anti-VEGF IVI.

Finally, a prior pars plana vitrectomy has been performed. The surgery results in a vitreous cavity filled with aqueous humor that is more fluid than vitreous humor and, probably, more prone to leak.

All the ocular conditions created a significant scleral fragility that promoted abnormal reflux, leading to a marked hypotony and consequent hypotony maculopathy and vision loss. Topical treatment is not always sufficient, with more severe cases needing a scleral suture to solve it.

Hypotony maculopathy should be taken into consideration when performing IVI. The need to continue anti-VEGF treatment imposes care with the procedure site, which should be alternated in each administration, to avoid more scleral damage. Also, a perpendicular needle entry in the sclera should be avoided in favor of a more oblique approach, reducing the incidence of blebs in the entry site, and consequent fluid reflux.¹⁰

Conclusion

Despite being a popular procedure with a good safety profile, care should be taken when performing an IVI, specially in eyes with thin scleras and previous vitrectomies. Hypotony maculopathy, a sight-threatening condition, is not an adverse effect commonly associated with this procedure. However, it should be considered and prevented in pathologic eyes.

International Medical Case Reports Journal**Dovepress****Publish your work in this journal**

The International Medical Case Reports Journal is an international, peer-reviewed open-access journal publishing original case reports from all medical specialties. Previously unpublished medical posters are also accepted relating to any area of clinical or preclinical science. Submissions should not normally exceed 2,000 words or 4 published pages including figures, diagrams and references. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
