Abstract: Silver nanoparticles (AgNPs) of a small size were successfully synthesized using the wet chemical reduction method into the lamellar space layer of montmorillonite/chitosan (MMT/Cts) as an organomodified mineral solid support in the absence of any heat treatment. AgNO3, MMT, Cts, and NaBH4 were used as the silver precursor, the solid support, the natural polymeric stabilizer, and the chemical reduction agent, respectively. MMT was suspended in aqueous AgNO3/Cts solution. The interlamellar space limits were changed (d-spacing = 1.24–1.54 nm); therefore, AgNPs formed on the interlayer and external surface of MMT/Cts with d-average = 6.28–9.84 nm diameter. Characterizations were done using different methods, ie, ultraviolet-visible spectroscopy, powder X-ray diffraction, transmission electron microscopy, scanning electron microscopy, energy dispersive X-ray fluorescence spectrometry, and Fourier transform infrared spectroscopy. Silver/montmorillonite/chitosan bionanocomposite (Ag/MMT/Cts BNC) systems were examined. The antibacterial activity of AgNPs in MMT/Cts was investigated against Gram-positive bacteria, ie, Staphylococcus aureus and methicillin-resistant S. aureus and Gram-negative bacteria, ie, Escherichia coli, E. coli O157:H7, and Pseudomonas aeruginosa by the disc diffusion method using Mueller Hinton agar at different sizes of AgNPs. All of the synthesized Ag/MMT/Cts BNCs were found to have high antibacterial activity. These results show that Ag/MMT/Cts BNCs can be useful in different biological research and biomedical applications, including surgical devices and drug delivery vehicles.

Keywords: silver nanoparticles, bionanocomposites, montmorillonite, chitosan, antibacterial activity, Mueller Hinton agar

Introduction

In recent years, silver nanoparticles (AgNPs) have attracted considerable attention for medical and chemical applications due to their exceptional properties, including antibacterial activity, high resistance to oxidation, and high thermal conductivity.1–5 Recently, different inorganic antibacterial materials, including AgNPs, have been expanded and some are in commercial use.6 The antibacterial activity of AgNPs-containing materials can be used, for example, in medicines to treat infections in human skin,7,8 dental materials,9 catheters,10,11 vascular grafts,12 stainless steel materials,13 arthroplasty,14 and burn treatment,15,16 as well as to prevent microorganism colonization on prostheses.17 In addition, nanomaterials including AgNPs can be utilized for water treatment18 and also for reducing bacteria on textile fabrics.19,20 AgNPs also have effective cytoprotective activity towards human immunodeficiency virus-infected cells.21 Because of this broad variety of applications, many preparation methods have
been developed. In addition to the bactericidal effects of Ag ions, the antimicrobial activity of colloid AgNPs is influenced by the size of the particles, ie, the smaller the particles, the greater the antimicrobial effect.22–28 Therefore, in developing methods for AgNP preparation, it is important to control the size of the AgNP particles. AgNPs of small size and devoid of aggregation properties are favorable for this purpose.

Chemical reduction methods have been widely investigated for the synthesis of AgNPs because these techniques can be executed under easy and gentle conditions, and can be used to synthesize AgNPs on a large scale. The reducing capability of a reductant has a significant role in the synthesis of AgNPs by the reduction reaction. The use of a strong reducing agent, such as NaBH4, results in tiny particles that are well dispersed.29

Nowadays, a succession of chemical reductants can be used for the synthesis of noble metal nanoparticles which contain NaBH4,30,31,36 NH2OH,32 NH2,33,36 (CH3)2 NH-BH3,34 H2,35 formaldehyde,36 formamide,37 Tollens’ reagents,38 ethylene glycol,39 ethanol,40 citrate,42,43 aniline,41 polyamylamine,42 or ascorbic acid.43

Layered silicates, eg, montmorillonite (MMT), have been used in polymer nanocomposites with a significant improvement in mechanical properties.44,45 MMT possesses a 2-to-1 layered structure with a single octahedral aluminum layer located between two layers of tetrahedral silicon.46 Each layer is about 1 nm thick with a lateral dimension of 100–1000 nm.47 Furthermore, being a lamellar clay, MMT has intercalation, swelling, and ion exchange properties.48 MMT can be delaminated into elemental sheets without difficulty. Therefore, it is tempting to utilize these sheets as the substrate for preparation of nanoscale metals by means of electrodeless plating. The MMT interlayer space has been used for the synthesis of material and biomaterial nanoparticles as the support for anchoring transition metal complexes and as adsorbents for cationic ions.49,50

Among the natural polymers, chitosan (Cts) has been extensively investigated as a natural cationic biopolymer because of its excellent biocompatibility, biodegradability, nontoxicity, bioactivity, and multifunctional groups, as well as its solubility in aqueous medium for food packaging film, bone substitutes, and artificial skin.51 Cts can be intercalated in MMT by cationic exchange and hydrogen bonding processes, whereby the resulting bionanocomposites (BNCs) show interesting structural and functional properties.52 Conversely, BNCs are made of a natural polymeric matrix and inorganic/organic filler with at least one dimension on the nanometer scale. Metal/clay/polymer compounds like BNCs with their excellent properties have become a promising new areas of research.53

Furthermore, AgNPs have long been known to have strong inhibitory and bactericidal effects, as well as a broad spectrum of antimicrobial activity, and have been used for centuries to prevent and treat a variety of diseases, most notably infections. AgNPs were reported recently as having antibacterial activity against Escherichia coli, Staphylococcus aureus, methicillin-resistant Staphylococcus epidermis, and methicillin-resistant S. aureus (MRSA) bacteria.53–55 AgNPs also exhibit potent cytoprotective activity towards cells infected with human immunodeficiency virus.56 The application of AgNPs for biological labelling in neuroblastosoma cells was recently reported. Due to the strong plasmon-resonant properties of AgNPs and the enhanced resolution obtainable with high-illumination systems in physiological solution, studies of the interactions between AgNPs and human cells have been possible.57 Hence, similar studies on Ag/poly(lactic acid),50 Ag/MMT,48,59 Ag/talc,58 Ag/MMT/ starch BNCs60 and Ag/MMT/Cts BNCs,51,52 have been undertaken previously.

In this research, the spherical structure of AgNPs was synthesized in the interlayer surface of the MMT layers modified with a low percentage of Cts in aqueous solution by using AgNO3, Cts, and NaBH4 as the silver precursor, the stabilizer, and the reduction agent, respectively, at room temperature. We used modified clay (MMT/Cts) as the protective colloid to prevent the AgNPs from aggregating, and it was found that MMT/Cts also assisted in the chemical reduction process of silver. Needless to say, to date, there has not been any report of a study of Ag/MMT/Cts BNCs using a chemical reduction method, ie, lamellar polymeric silicate, which is the subject of this research. In addition, the antibacterial activity of AgNO3/MMT/Cts and Ag/MMT/Cts BNCs were investigated and compared. Using this method, we were able to obtain AgNPs of different sizes and dissimilar antibacterial activity by controlling the AgNO3 concentration.

**Materials and methods**

**Chemicals**

All reagents in this work were of analytical grade and used as received without further purification. AgNO3 (99.98%), used as the silver precursor, was obtained from Merck (Darmstadt, Germany). Meanwhile, the MMT powder, used as a solid support for the AgNPs, was purchased from Kunipia-F (Tokyo, Japan). NaBH4 (98.5%), low-molecular-weight Cts, and glacial acetic acid (99%) used as a reduction agent, a stabilizer, and for solubilizing Cts, respectively, were obtained from...
Silver/montmorillonite/chitosan bionanocomposites

Sigma-Aldrich (St Louis, MO). All the aqueous solutions were used with double-distilled water.

Synthesis of Ag/MMT/Cts BNCs using NaBH₄

For the synthesis of Ag/MMT/Cts BNCs, soluble Cts (100 mL, 0.5 wt%) was prepared by solubilization in 1.0 wt% of acetic acid solution (pH ~3.53) under constant stirring for 45 minutes, for each of the samples. Following the usual preparation method for AgNPs, AgNO₃ solutions were added to each soluble Cts sample under constant stirring for synthesis of the AgNO₃/Cts solutions. The aqueous Cts-acetic acid solution thickened after the addition of AgNO₃ solution. The Ag content of the samples was 0.5 (A1), 1.0 (A2), 1.5 (A3), 2.0 (A4), and 5.0 g (A5) Ag/100 g MMT. Constant amounts of MMT were suspended in different volumes of 1 × 10⁻³ M AgNO₃ solution with soluble Cts and stirred for 24 hours at room temperature to obtain the AgNO₃/MMT/Cts suspensions. Freshly prepared NaBH₄ (4 × 10⁻² M) solution was then added to the suspensions under continuous stirring to reach a constant AgNO₃/NaBH₄ molar ratio (1:4). After the addition of the reducing agent, stirring was continued for another hour. The suspensions of Ag/MMT/Cts BNCs obtained were then centrifuged, washed four times using double-distilled water to remove the silver ion residue, and dried at 40°C under vacuum overnight. All the experiments were conducted at ambient temperature.

Evaluation of antibacterial activity

The in vitro antibacterial activity of the samples was evaluated by the disc diffusion method using Mueller Hinton agar with determination of inhibition zones, which conformed to the recommended standards of the National Committee for Clinical Laboratory Standards (now known as the Clinical and Laboratory Standards Institute, 2000). E. coli (ATCC 25922), E. coli O157:H7 (ATCC 43895), Pseudomonas aeruginosa (ATCC 10145), S. aureus (ATCC 25923), and MRSA (ATCC 700689) were used for the antibacterial assay. Briefly, 6 mm sterile paper discs impregnated with 20 µL of Ag/MMT/Cts BNCs (A2, A4, and A5) with different treatment times were suspended in the sterile distilled water and left to dry at 37°C for 24 hours under sterile conditions. The bacterial suspension was prepared by making a saline suspension of isolated colonies selected over 18–24 hours of tryptic soy agar plate. The suspension was adjusted to match the tube of 0.5 McFarland turbidity standard using the spectrophotometer at 600 nm, which is equivalent to 1.5 × 10⁹ colony-forming units/mL. The surface of the Mueller Hinton agar was completely inoculated using a sterile swab, and was then steeped in the prepared suspension of bacterium. Finally, the impregnated discs were placed on the inoculated agar and incubated at 37°C for 24 hours. After incubation, the diameter of the growth inhibition zones was measured. Chloramphenicol 30 µg and cefotaxime 30 µg were used as the positive standards in order to control the sensitivity of the bacteria. All tests were done in triplicate.

Characterization methods and instruments

The prepared Ag/MMT/Cts BNCs were characterized by ultraviolet (UV)-visible spectroscopy, powder X-ray diffraction (PXRD), transmission electron microscopy (TEM), scanning electron microscopy (SEM), energy dispersive X-ray fluorescence spectrometry (EDXRF), inductively coupled plasma-optical emission spectrophotometer (ICP-OES), and Fourier transform infrared (FT-IR) spectroscopy. The UV-visible spectra were recorded over the 300–700 nm range utilising the Shimadzu H.UV.1650 PC spectrophotometer. The structures of the Ag/MMT/Cts BNCs produced were examined by powder X-ray diffraction using the Shimadzu PXRD-6000. Changes in the interlamellar spacing of MMT and Ag/MMT/Cts BNCs were also studied by PXRD in the angle range of 2θ < 2θ < 12°. In addition, the interlamellar spaces were calculated from the PXRD peak positions using Bragg’s law. A wavelength (λ) of 0.15418 nm was used for these measurements. The PXRD patterns were recorded at a scan speed of 2° min⁻¹. TEM observations were carried out on a H-7100 electron microscope (Hitachi, Tokyo, Japan), and the particle size distributions were determined using the UTHSCSA Image Tool program (version 3.00; Dental Diagnostic Science, UTHSCSA, San Antonio, TX). SEM was performed using the Philips XL-30 instrument (Philips, Eindhoven, The Netherlands) to study the morphology of MMT, MMT/Cts, and Ag/MMT/Cts BNCs (A2, A4, and A5). EDXRF was carried out on a EDX-700HS spectrometer (Shimadzu, Osaka, Japan). Elemental analysis of the synthesized AgNPs was quantified using an ICP-OES, model Optima 2000DV (Perkin Elmer, Waltham, MA). Meanwhile, the FT-IR spectra were recorded over the range of 400–4000 cm⁻¹ using the Series 100 Perkin Elmer FT-IR 1650 spectrophotometer. After the reactions, the samples were centrifuged using a high-speed centrifuge machine (Avanti J25; Beckman, Brea, CA).
Results and discussion

To prepare the stable AgNPs via the wet chemical reduction method, it was important to choose a suitable stabilizer and reducing agent. In this research, a MMT/Cts suspension was used as the appropriate support for reducing AgNO₃/MMT/Cts suspension, and using NaBH₄ as the strong reducing agent. AgNO₃ was reduced by NaBH₄ in the presence of MMT hydride with Cts (MMT/Cts), resulting in AgNPs prepared according to the following equation:\(^6\)

\[
\text{Ag}^{+}/\text{MMT/Cts} + \text{BH}_4^- + 3\text{H}_2\text{O} \rightarrow \text{Ag}^{0}/\text{MMT/Cts} + \text{B(OH)}_3^- + 3.5\text{H}_2 \uparrow
\]

The schematic illustration of the synthesis of Ag/MMT/Cts BNCs from AgNO₃/MMT/Cts produced using NaBH₄ as the chemical reduction agent is shown in Figure 1. Meanwhile, as shown in Figure 2, the MMT and AgNO₃/MMT/Cts suspensions (A0) were colorless, but after the addition of the reducing agent to the suspensions, they turned light brown (A1), brown (A2), reddish-brown (A3), and dark brown (A4 and A5), indicating the formation of AgNPs in the MMT/Cts suspensions. The formation of AgNPs was also followed by measuring the surface plasmon resonance bands of the AgNO₃/MMT/Cts (A0) and Ag/MMT/Cts BNCs suspensions (A1–A5) at wavelengths in the 300–700 nm range (Figure 3). The comparison between the PXRD patterns of MMT, MMT/Cts, and Ag/MMT/Cts BNCs (A1, A2, and A5) in the small angle range of \(2\theta (2^\circ < 2\theta < 12^\circ)\) indicated the formation of the intercalated AgNPs structure (Figure 4). In addition, the PXRD patterns in the wide angle range of \(2\theta (30^\circ < 2\theta < 80^\circ)\) were also employed to determine the crystalline structures of the synthesized AgNPs (Figure 5). The TEM images and size distribution of the AgNPs showed that the mean diameter of the nanoparticles ranged from about 6.28 nm to 9.84 nm (Figure 6). As shown in Figures 7 and 8, the SEM images indicated that there were no structural changes between the initial MMT, MMT/Cts, and Ag/MMT/Cts BNCs (A2, A4, and A5) at different AgNO₃ concentrations. In addition, the EDXRF spectra for the MMT, MMT/Cts and Ag/MMT/Cts BNCs (A2, A4, and A5) confirmed the presence of elemental compounds in MMT, Cts, and AgNPs without any other impurity peaks (Figures 7 and 8). The chemical structures of MMT, MMT/Cts, and Ag/MMT/Cts BNCs (A2, A4, and A5) were analyzed by FT-IR spectroscopy (Figures 9 and 10). The approximate efficiency gradually increased from A1 to A5, respectively (Table 1). The antibacterial studies showed comparatively similar effects for all samples, as indicated by the inhibition zone test between Cts, MMT/Cts, MMT, AgNO₃/MMT/Cts (A0), and Ag/MMT/Cts BNCs (A1–A5).
and Ag/MMT/Cts BNCs (A2, A4, and A5) against different bacteria (Figure 11, Table 2).

Ultraviolet-visible spectroscopy

The color of the AgNO₃/MMT/Cts suspensions through the reduction process using NaBH₄ changed from colorless to light brown, brown, reddish-brown, and, finally, dark brown (A1–A5), respectively, which indicated the formation of AgNPs in the MMT/Cts suspension. The silver surface plasmon resonance bands were detected around 391–408 nm (Figure 3). These absorption bands were assumed to correspond to AgNPs smaller than 10 nm. While there was no UV-visible absorption of AgNPs before the addition of NaBH₄ in A0 (Figure 3), the growth of the plasmon peak at 391 nm indicated the formation of AgNPs in A1. Furthermore, the gradual increase in the AgNO₃ concentration from A1 to A4 also increased the corresponding peak intensities in the wavelength range of 391–403 nm. In A5, the absorption peak due to surface plasmon resonance of Ag⁺ was slightly red-shifted to a higher wavelength (408 nm), which indicated the increase in size of the AgNPs.65,66

Powder X-ray diffraction

As shown in Figure 4, the original d-spacing (d₀) of MMT (1.24 nm) and in MMT/Cts, was increased to 1.45 nm at the small 2θ angles (2θ = 7.12° for MMT and 2θ = 6.09° for MMT/Cts) by Cts intercalation. The d₀ in A2, A4, and

![Figure 2](image-url)  Photograph of montmorillonite/chitosan bionanocomposite suspension (A0) and silver/montmorillonite/chitosan bionanocomposite suspension at different AgNO₃ concentrations: (A1) 0.5%, (A2) 1.0%, (A3) 1.5%, (A4) 2.0%, and (A5) 5.0%.

![Figure 3](image-url)  Ultraviolet-visible absorption spectra of silver/montmorillonite/chitosan bionanocomposite suspension for different AgNO₃ concentrations: (A1) 0.5%, (A2) 1.0%, (A3) 1.5%, (A4) 2.0%, (A5) 5.0%, and (A0) silver nitrate/montmorillonite/chitosan bionanocomposite suspension in the absence of sodium borohydride.
A5 also increased gradually from 1.49 nm to 1.51 nm and finally to 1.54 nm at the 20 angles (2θ = 5.98° [A1], 2θ = 5.96° [A4], and 2θ = 5.90° [A5]) by Ag/Cts intercalation between MMT layers. These d_S values were direct proof of the intercalation structures. The AgNPs formed at the latter location were the cause of the increase in basal spacing. In these samples, the intensities of the reflections were significantly lower, whereas their half-widths were larger than those of undoped clay minerals, whereby the highly ordered parallel lamellar structure of the mineral was disrupted by metal nanoparticle formation.67 In addition, all the Ag/MMT/Cts BNCs (A1–A5) had a similar diffraction profile, and the PXRD peaks at 2θ of 38.32°, 44.48°, 64.62°, and 77.60° (Figure 5) could be attributed to the 111, 200, 220, and 311 crystallographic planes of the face-centered cubic silver crystals, respectively.68 For all samples, the main crystalline phase was silver, and no other obvious phases were found as impurities in the PXRD patterns. Moreover, the PXRD peak broadenings of the AgNPs were mostly due to the existing nanosized particles in the BNPs. In addition, there was a characteristic peak at about 2θ = 62.30° related to the MMT clay (PXRD Ref No 00–003–0010) as a stable substrate. The intensities of 111, 200, 220, and 311 reflections due to the AgNP phase were also found to increase along with the increased AgNPs in the solid support matrix content stabilizer (MMT/Cts) by the wet chemical reduction method.

Morphology

The TEM images and their corresponding particle size distributions for the Ag/MMT/Cts BNCs containing different percentages of AgNPs are shown in Figure 6. The TEM images and their size distributions reveal that the mean diameters and standard deviation of the AgNPs were about 6.28 ± 3.54, 8.29 ± 3.18, and 9.84 ± 2.51 nm for 1.0% (A-B), 2.0% (C-D) and 5.0% (E-F), respectively. These results showed that the diameters of the AgNPs synthesized by this method depended on the initial AgNO3 concentration. SEM images of the MMT, MMT/Cts, and Ag/MMT/Cts (A2, A4, and A5) are presented in Figures 7 and 8. The surface morphology of MMT demonstrates a layered surface with some large flakes, which is the typical structure for MMT (Figure 7A). The exterior morphology of the MMT/Cts and Ag/MMT/Cts BNCs (A2, A4, and A5) are presented in Figures 7 and 8. The surface morphology of MMT demonstrates a layered surface with some large flakes, which is the typical structure for MMT (Figure 7A). The exterior morphology of the MMT/Cts and Ag/MMT/Cts BNCs (A2, A4, and A5) show layered surfaces with large flakes and without significant morphological differences between them. Furthermore, the external surfaces of Ag/MMT/Cts BNCs (A2, A4, and A5) gradually become more shiny due to the presence and increase of AgNP amounts.
Silver/montmorillonite/chitosan bionanocomposites

Figure 6 Transmission electron microscopy images and corresponding particle size distribution of silver/montmorillonite/chitosan bionanocomposites at different AgNO₃ concentrations: 1.0% (A, B), 2.0% (C, D), and 5.0% (E, F).

(Figures 8 A, B, and C). Figure 7 (B, D) shows the EDXRF spectra for the MMT and MMT/Cts. The peaks at around 1.7, 2.7, 2.9, 3.7, 4.0, 4.5, 6.4, and 7.1 keV are related to the binding energies of MMT, and peaks at around 8.1, 8.7, and 9.6 keV correspond to the binding energies of Cts. In Figure 8D, the peaks around 1.3, 3.1, 3.3, and 3.4 keV are related to Ag⁺ elements in A2, A4, and A5. In addition, the EDXRF spectra for the MMT, MMT/Cts, and Ag/MMT/Cts BNCs (A2, A4, and A5) confirmed the presence of elemental compounds in the MMT, Cts, and AgNPs without any impurity peaks.
Figure 7 Scanning electron microscopy micrographs and energy dispersive X-ray fluorescence spectra for montmorillonite (A, B) and montmorillonite/chitosan (C, D), respectively. Abbreviations: Cts, chitosan; MMT, montmorillonite.

Figure 8 Scanning electron micrographs and energy dispersive X-ray fluorescence spectra, respectively, for the silver/montmorillonite/chitosan bionanocomposites at different AgNO₃ concentrations: 1.0% (A), 2.0% (B), 5.0% (C), and (D). Abbreviation: AgNPs, silver nanoparticles.
Figure 8D also demonstrates that, with the increased percentages of AgNPs in MMT/Cts (1%, 2%, and 5%) and after reduction, the intensity of AgNP peaks in the EDXRF spectra increased. The results indicate that the synthesized BNCs are composed of high-purity Cts and AgNPs.

Chemical analysis by Fourier transform infrared spectroscopy

The FT-IR spectrum of MMT (Figure 9C) show the vibration bands at 3633 cm$^{-1}$ for O-H stretching, 3447 cm$^{-1}$ due to the interlayered O-H stretching (H bonding), at 1652 and 1531 cm$^{-1}$ for H-O-H bending, 1126, 1011, and 910 cm$^{-1}$ for Si-O stretching, 624 cm$^{-1}$ for Al-OH, 910 cm$^{-1}$ due to (Al, Mg)-OH vibration modes and 527 and 446 cm$^{-1}$ for Si-O bending. The spectrum of Cts (Figure 9A) show peaks at 3375 and 3320 cm$^{-1}$ due to the overlapping of O-H and N-H stretching bands, ie, 2900 cm$^{-1}$ for aliphatic C-H stretching, 1652 and 1612 cm$^{-1}$ for N-H bending, 1434, 1386, and 1333 cm$^{-1}$ for C-H bending, and 1051 cm$^{-1}$ for C-O stretching. The spectrum of MMT/Cts (Figure 9B) shows a combination of characteristic absorptions due to MMT and the amine groups of Cts. The peaks of the external vibration and interlayered stretching O-H groups in MMT and MMT/Cts were relatively constant at 3634, and a little shifted to low wave numbers in 3424 cm$^{-1}$. On the other hand, the peaks of aliphatic C-H and -NH$_2$ groups in pure Cts at 2900, 1652, and 1612 cm$^{-1}$ were shifted to 2887, 1647, and 1538 cm$^{-1}$ in the MMT/Cts, corresponding to the deformation vibration of the amine group of Cts.$^{71,72}$ These results appeared to be in agreement with the data from PXRD, revealing the intercalation of Cts in the MMT structure.

As shown in Figure 10, there were changes in the spectra of Ag/MMT/Cts BNCs compared with MMT/Cts (Figure 9) and peaks in A2, A4, and A5 shifted to lower wave numbers. The FT-IR spectra demonstrated the inflexibility of the silicate layers and the nonbonding chemical interface between the silicate layers and AgNPs in Ag/MMT/Cts BNCs (A2, A4, and A5). The interactions between the silicate layers of MMT and Cts were related to the peaks at the high and low wave numbers. For example in A2, a peak at 2946 cm$^{-1}$ is associated with aliphatic C-H stretching, 1649 cm$^{-1}$ is related to the overlap Cts peaks in 1652 and 1612 cm$^{-1}$, with a MMT peak in 1652 cm$^{-1}$. Moreover, peaks appear in 1448, 1396, and 1330 cm$^{-1}$ connected with C-H bending, similar to the Cts peaks. Broad peaks were due to the presence of van der Waals interactions between the hydroxyl, amine, and C-H bending groups of Cts intercalated to the MMT layers with a partial positive charge on the surface of the AgNPs.$^{61}$ These results confirm that, with the increased amounts of AgNPs in the Ag/MMT/Cts BNCs (A2, A4, and A5), respectively, due to the existence of complexation peaks between the Cts groups and AgNPs, the peaks are shifted to low wave numbers and the peak intensity is increased.

![Figure 9](image-url) Fourier transform infrared spectra for chitosan (A), montmorillonite/chitosan (B), and montmorillonite (C), respectively.
Inductively coupled plasma-optical emission spectroscopy

The ICP-OES analyzer was used to determine the approximate efficiency of AgNO₃/MMT/Cts suspension reduction by NaBH₄ to Ag/MMT/Cts BNCs. A modified digestion method was used to quantify the amount of AgNP conversion to Ag⁺ in the MMT/Cts. An air-dried mass of each Ag/MMT/Cts BNC sample (A1–A5) was submerged in a solution of 10 mL of ultrapure reagent grade nitric acid (364576, grade ≥90%; Sigma-Aldrich), and 10 mL of double-distilled water. After the samples were placed over the digestion beakers, the solutions were heated to approximately 80°C for 15 minutes and allowed to react. The digestion solutions were allowed to cool in room temperature and then filtered through a glass fiber filter (Qualitative #2; Whatman, Florham Park, NJ) and diluted in 100 mL in volumetric flasks. After detecting the Ag⁺ ions by ICP-OES spectroscopy, with the increased concentration of AgNO₃ in the MMT/Cts matrix and then the reduction by the reducing agent, the approximate efficiency gradually decreased from 97.20% to 95.35%, 92.47%, 88.53%, and, finally, 83.50% after A1, A2, A3, A4, and A5, respectively (Table 1). The results from the ICP-OES analysis using a strong reduction agent confirmed the formation of AgNPs in MMT/Cts, which produced high yields.

Antibacterial activity

Inhibition zone values were obtained for the synthesized AgNO₃/MMT/Cts suspension and Ag/MMT/Cts BNCs (A2, A4, and A5) tested against E. coli, E. coli O157:H7, and...
P. aeruginosa, S. aureus, and MRSA. The results and images of the inhibition zones are presented as average values in Table 2 and Figure 11, respectively. Table 2 shows that the AgNO₃ and AgNPs in MMT/Cts suspension had high and similar antibacterial activity against Gram-negative and Gram-positive bacteria. Because of their size, AgNPs can easily reach the nuclear content of bacteria and they show a large and impressive surface area, where contact with bacteria is the greatest.74,75 This could be the reason why these nanoparticles have the best antibacterial effect. For solid support systems, some researchers argue that Ag⁺ ions released from the surface of AgNPs are responsible for their antibacterial activity.76,77 For aqueous phase systems, the results show that the antibacterial test of Ag⁺ ions is not high at the concentration levels reached by release, and the presence of AgNPs is very important, which reinforces the idea that the larger the surface area, the greater the antibacterial activity.78 The diameters of the inhibition zones in agar plates are given in mm. The tests were repeated three times for each treated sample, and the results are presented in Table 2. The suspensions of MMT (10 mg/mL), soluble Cts (0.5 mg/mL), and MMT/Cts did not show any antibacterial activity. The AgNO₃/MMT/

Cts suspension for all tested bacteria shows high antibacterial activity and, interestingly, these effects in the Ag/MMT/Cts BNCs (A2, A4, and A5) were increased with decreasing size of AgNPs. However, this research also showed that the amounts of AgNPs gradually were increased in the Ag/MMT/Cts BNCs (A2, A4, and A5), but higher AgNPs loading does not lead to superior antibacterial activity.

Conclusion

AgNPs were successfully prepared from AgNO₃/MMT/Cts suspension at different AgNO₃ concentrations by using NaBH₄ as a chemical reduction agent in the interlamellar space and external layer surface of MMT modified with Cts without any heat treatment or reducing agent. These AgNPs were found to be stabilized by the low molecular weight of Cts. In addition, the distribution size of AgNPs prepared at different concentrations of AgNO₃ indicate that larger particle sizes of AgNPs were obtained when the Ag⁺ ion concentration increased. The average diameters of the AgNPs were around 6.28, 8.29, and 9.84 nm for A2, A4, and A5, respectively. Moreover, the PXRD analysis confirmed that the crystallographic planes of the silver crystals were of the face-centered cubic type. The UV-visible absorption spectra showed the peak characteristics of the surface plasmon resonance bond of AgNPs. SEM images show that the external morphology for MMT, Cts, and Ag/MMT/Cts BNCs (A2, A4, and A5) have layered surfaces with large flakes, with no noteworthy morphological distinctions between them. Also, due to the presence of AgNPs in the external and internal surfaces of Ag/MMT/Cts BNCs, these layers become shiny. EDXRF spectra confirmed the presence of elemental compounds in the MMT, Cts, and AgNPs without any contamination peaks. The antibacterial activities of Ag/MMT/Cts BNCs at the different AgNP particle sizes showed strong antibacterial activity against Gram-positive and Gram-negative bacteria. These results show that the antibacterial resistance of AgNPs in MMT/Cts can be modified according to the size of AgNPs, and decreases with increased particle size. Further studies are required to investigate the bactericidal effects of Ag/MMT/Cts BNCs against different types of bacteria for potential widening of their applications, such as in surgical devices and in drug-delivery vehicles.
