Purpose: Anaplastic lymphoma kinase (ALK) inhibitors are associated with good overall survival (OS) for ALK-positive metastatic non–small cell lung cancer (NSCLC). However, these treatments can be unavailable or limited by financial constraints in developing countries. Using data from a nationwide lung cancer registry, the present study aimed to identify treatment patterns and clinical outcomes of ALK-positive NSCLC in Malaysia.

Methods: This retrospective study examined data of patients with ALK-positive NSCLC from 18 major hospitals (public, private, or university teaching hospitals) throughout Malaysia between January 1, 2015 and December 31, 2020 from the National Cardiovascular and Thoracic Surgical Database (NCTSD). Data on baseline characteristics, treatments, radiological findings, and pathological findings were collected. Overall survival (OS) and time on treatment (TOT) were calculated using the Kaplan–Meier method.

Results: There were 1581 NSCLC patients in the NCTSD. Based on *ALK* gene-rearrangement test results, only 65 patients (4.1%) had ALK-positive advanced NSCLC. Of these 65 patients, 59 received standard-of-care treatment and were included in the analysis. Crizotinib was the most commonly prescribed ALK inhibitor, followed by alectinib and ceritinib. Patients on ALK inhibitors had better median OS (62 months for first-generation inhibitors, not reached at time of analysis for second-generation inhibitors) compared to chemotherapy (27 months), but this was not statistically significant ($P=0.835$) due to sample-size limitations. Patients who received ALK inhibitors as first-line therapy had significantly longer TOT (median of 11 months for first-generation inhibitors, not reached for second-generation inhibitors at the time of analysis) compared to chemotherapy (median of 2 months; $P<0.01$).

Conclusion: Patients on ALK inhibitors had longer median OS and significantly longer TOT compared to chemotherapy, suggesting long-term benefit.

Keywords: ALK inhibitors, chemotherapy, ALK-positive, NSCLC

Introduction

ALK gene translocation is a common genetic aberration in patients with lung cancer.¹ Studies in both Western and Asian populations have revealed that about 4%–5% of non–small cell lung cancer (NSCLC) patients harbor *ALK* translocations.^{1–7} In one Asian study, the prevalence of *ALK* translocations in NSCLC patients was up to 6.7% of

NSCLC patients.^{1,2} Patients who harbor *ALK* translocations are likely to be young (<50 years old), female, nonsmokers, or have adenocarcinoma.⁸

ALK genetic aberrations are diagnosed with tumor-cell testing via immunohistochemistry (IHC), fluorescence in situ hybridization (FISH), reverse-transcription polymerase chain reaction, or fusion transcription (RNA next-generation sequencing).^{6,9–11} While FISH is the gold-standard test for detecting *ALK* rearrangements, IHC is cost-effective and easier to incorporate into the routine laboratory workflow.¹² A local study showed that IHC is a reliable and practical test for *ALK* expression.¹³ The average turnaround time for FISH is 2–5 days, while the turnaround time for IHC is 1–2 days.¹⁴

Patients with *ALK* translocations are increasingly being treated with targeted therapies (*ALK* inhibitors). Crizotinib, a first-generation *ALK* inhibitor, was approved by the US Food and Drug Administration (FDA) in 2011, by the European Medicines Agency (EMA) in 2012, and in Malaysia in 2012. Ceritinib, a second-generation *ALK* inhibitor, was approved by the FDA in 2014, by the EMA in 2015, and in Malaysia in 2016. The FDA approved alectinib, another second-generation *ALK* inhibitor in 2015; while in Malaysia, alectinib was approved in 2018. These *ALK* inhibitors are associated with significantly better progression-free survival (PFS) than chemotherapy, with second-generation *ALK* inhibitors having significantly better PFS than first-generation inhibitors.¹⁵ However, *ALK* inhibitors can be unavailable or limited by cost constraints in developing countries. A budget analysis from a neighboring country, Thailand, revealed that only affluent patients could afford an *ALK* inhibitor.¹⁶ Even in the USA, the use of these treatments is associated with high economic burden.¹⁷ The objectives of this retrospective study were to assess clinical outcomes and treatment patterns among advanced NSCLC patients harboring *ALK* translocations in Malaysia based on data from a nationwide lung cancer registry.

Methods

Study Design and Data Sources

All procedures were carried out in accordance with relevant guidelines and regulations. The authors are accountable for all aspects of the work in ensuring that questions related to the accuracy or integrity of any part of the work are appropriately investigated and resolved. The study was reviewed and approved by the Universiti Malaya Medical Centre Medical Research Ethics Committee (MECID 20201115–9217). The committee waived the need for informed consent, as patient confidentiality was preserved using identification code numbers. The study was also performed in accordance with the principles stated in the Declaration of Helsinki.

This retrospective study used the National Cardiovascular and Thoracic Surgical Database (NCTSD), a nationwide hospital database that captures detailed information on the diagnosis and management of adult lung cancer patients (age ≥ 18 years) in Malaysia with a diagnosis of primary lung cancer (confirmed cytologically or histologically). Eighteen major hospitals throughout Malaysia, included public, university, and private hospitals, contribute data to the registry via an electronic case report form (eCRF). The eCRF was developed by the participating investigators, who consisted of oncologists, surgeons and respiratory physicians. Each source-data provider accessed its own data, and only authorized users (investigator or other members of the study team) were allowed to enter data remotely at their site via a web application. All data were de-identified to protect patients' privacy.

For this study, patients from the registry with advanced stage IIIB, IIIC, or IV NSCLC harboring *ALK* translocations were included. Data on diagnosis date, age, sex, ethnicity, smoking status, Eastern Cooperative Oncology Group (ECOG) performance status, staging, histology, radiology findings, pathological findings, and treatment records (including type of drugs, duration of treatment, and line of therapy) were analyzed.

Study Population

In this study, eligible patients were ≥ 18 years at the time of diagnosis, had advanced stage IIIB, IIIC, or IV NSCLC with positive *ALK*-rearrangement test results on FISH or IHC, and had been included in the registry database between January 1, 2015 and December 31, 2020. Patients had at least one measurable lesion as per Response Evaluation Criteria in Solid Tumors version 1.1 and ECOG performance-status score of 0–4 with adequate organ function. Staging was done with contrast-enhanced CT of the thorax and whole abdomen with/without bone scan (when indicated) or whole-body FDG-PET

/CT. Symptomatic patients were diagnosed using MRI of the central nervous system or according to the practice of the participating hospital. Patients with stage IIIA NSCLC were excluded, as surgery is indicated in this group of patients. The study population consisted of patients in both the public (including the university teaching hospitals) and private institutions.

Genomic Analysis

ALK gene arrangements detected by FISH used the break-apart probe on the *ALK* gene according to the manufacturer's instructions and analyzed using a fluorescence microscope equipped with orange, green, and 49,6-diamidino-2-phenylindole filters. If 15% of the tumor cells had a split red and green signal and/or a single red signal, the specimen was considered *ALK* FISH-positive. *ALK* gene arrangements were detected by IHC using an IHC detection kit according to the manufacturer's recommendations for the visualization of the bound primary antibody and analyzed using light microscopy. If the tumor cells had strong granular cytoplasmic brown staining, the specimen was considered *ALK*-positive. Specific numbers of patients were not captured, as there is a high level of concordance in *ALK*-positivity detection between IHC and FISH.¹⁸

Treatment

All patients in the study received standard-of-care treatment following international guidelines. Patients received at least one line of systemic therapy (chemotherapy or *ALK* inhibitor).

Outcome Variables

The demographic and clinical characteristics of patients were gathered. Comorbidities included hypertension, diabetes mellitus, and cardiovascular or chronic kidney disease. Type of treatment (chemotherapy or targeted therapy), time on treatment (TOT), disease progression, and overall survival (OS) were assessed. The primary end point was OS, defined as the time from initiation of therapy until death from any cause. The secondary end point was TOT, which was defined as the duration between the first day of therapy to the last day of therapy.

Statistical Analysis

Data were retrieved from the registry and screened for missing values. Any missing data were cross-examined by the site investigator. Data analysis was performed using SPSS version 23. Descriptive data are presented as percentages. Continuous data (age and TOT) are presented as medians. The duration of time is described in months. All *P* values reported are two-sided and considered significant at the 0.05 threshold. The Kaplan–Meier method was used to estimate the OS and TOT, and the log-rank test was used to test the survival differences between groups. Multivariate analysis was performed using Cox proportional hazard regression to determine the independent prognostic factors affecting survival. *P* < 0.05 was considered statistically significant. Univariate factors that were statistically significant were selected for the final model. HRs are given with 95% CIs.

Results

Baseline Demographic and Clinical Characteristics

There were 1581 NSCLC patients in the NCTSD. Based on *ALK* gene rearrangement test results (either FISH or IHC), 65 patients (4.1%) had advanced NSCLC with *ALK* translocations. Of the 65 *ALK*-positive patients, six were excluded because they died before *ALK* results were available (*n*=3), refused treatment (*n*=2), or the staging was not clear (*n*=1). A total of 59 patients received standard-of-care treatment and were included in the analysis. The median age of the patients was 55 (24–76) years. A majority (76.7%) were nonsmokers, 59.3% had no comorbidities, and 73.3% had an ECOG score of 0 or 1 (Table 1). Most patients had adenocarcinoma (93.2%) and stage IV disease (88.3%; Table 1).

Overall Survival

Patients on *ALK* inhibitors had better median OS (62 months for first-generation inhibitor, not reached for second-generation inhibitors) compared to chemotherapy (27 months; Table 2 and Figures 1 and 2), but this was not statistically significant (*P*=0.835, Figure 2). On subgroup analysis, patients with *ALK*-positive adenocarcinoma had significantly

longer median OS than those with ALK-positive non-adenocarcinoma (62 months versus 8 months, $P < 0.05$, Table 2). Patients on more than one ALK inhibitor had higher mean OS (57 months) than those who were only on one (26 months; Figure 3). However, this difference was not significant ($P = 0.079$). The OS data for the second-generation ALK inhibitors were not mature at the time of primary cutoff, and the median had not been reached.

Treatment Patterns

Of the 59 treated patients, eleven received first-line chemotherapy (cisplatin and pemetrexed) (Table 3). The remaining 48 patients were started on ALK inhibitors. Crizotinib was the most commonly prescribed ALK inhibitor (39.6%) followed by alectinib (33.3%) and ceritinib (27.1%). At the time of analysis, all eleven patients on first-line chemotherapy had progressed compared to only 19 (39.5%) patients on first-line ALK inhibitors (Table 3). All eleven patients who progressed on first-line chemotherapy went on to receive second-line treatment (Table 3). Approximately half (45.5%) of these patients received chemotherapy again as second-line treatment, while another half received ALK inhibitors.

Table 3 Overall response rate and time on treatment (n=59)

First-line treatment	n	ORR (%)	TOT (Month)	Second-line treatment ^a					
				Chemotherapy	Crizotinib	Ceritinib	Alectinib	Lorlatinib	None
Chemotherapy ^b	11	70	2	5	2	2	2	0	0
Crizotinib	19	82.4	10	1	0	10	1	0	7
Ceritinib	13	80	11	1	0	0	0	1	11
Alectinib	16	100	12	3	0	0	0	2	11

Notes: ^aFewer on second-line treatment than first-line treatment, as some were still on first-line treatment at the time of analysis; ^bcisplatin-based chemotherapy (n=10) and single-agent pemetrexed (n=1).

Abbreviations: ORR, overall response rate; TOT, time on treatment.

Majority of patients on first-line crizotinib (94.7%) received a second-generation ALK inhibitor as second-line treatment upon disease progression. At the time of analysis, two patients from this group went on to receive crizotinib as third-line treatment, and one patient received crizotinib as fourth-line treatment. No rebiopsies were performed when disease progressed on an ALK inhibitor.

Patients who received ALK inhibitors as first-line therapy had significantly longer TOT (11 months for first-generation inhibitors and median not reached at the time of analysis for second-generation inhibitors) compared to chemotherapy (2 months; $P<0.01$; Table 4 and Figure 4). The median TOT for ceritinib and alectinib as first-line therapy was not reached as most of the patients were still on first-line targeted treatment at the time of analysis. Majority of the patients who received alectinib were started on the drug at the end of 2019, when the drug was made available commercially.

Discussion

As there is a scarcity of clinical trial data on the use of ALK inhibitors in countries with limited resources,¹⁹ our retrospective data analysis provides real-world insights on treatment and outcomes of NSCLC patients with *ALK* translocations in a developing country — Malaysia. The median OS was longer for the first-generation ALK inhibitor crizotinib (62 months) compared to chemotherapy (27 months). The median OS for the second-generation ALK inhibitors (ceritinib and alectinib) had not been reached at the end of the study. However, there was no significant difference in the OS curves between the treatment arms ($P=0.835$). Likewise, in the PROFILE studies, those on the crizotinib arm showed significant improvements in their PFS compared to those on chemotherapy, but there was no difference in OS, which was postulated to have been caused by the crossover of participants between the two study arms at disease progression.¹⁵ In our study, 54.5% of patients who failed first-line chemotherapy went on to receive an ALK inhibitor.

In contrast, most patients who progressed on an ALK inhibitor in the first-line setting received another type of ALK inhibitor in the second-line setting instead of chemotherapy. These patients had longer OS than those who had received only one ALK inhibitor. Similarly, another real-world study showed that the use of more than one ALK inhibitor line significantly improved OS.²⁰

**Figure 4** Kaplan–Meier curves for time on treatment.

Notes: Patients were treated with chemotherapy or first/second-generation ALK inhibitors.

Abbreviations: ALK, anaplastic lymphoma kinase; TOT, time on treatment.

Patients on ALK inhibitors in our study had significantly longer TOT than those on chemotherapy, suggesting long-term benefit. In real-world NSCLC studies, TOT or time to treatment discontinuation can be used as a surrogate end point to assess the effectiveness of treatment, as it correlates with PFS and OS (as determined through analysis of randomized controlled trials).^{21–23} In another real-world study of NSCLC patients with *ALK* translocations, the median time to treatment failure (due to progression, death, or other reasons) for crizotinib was 10 months.²⁴ TOT for the first-generation ALK inhibitor (crizotinib) was slightly longer, 11 months, as some patients continued treatment with first-line ALK inhibitors despite disease progression. This is partly because a lot of patients prefer oral therapy over chemotherapy and second-generation ALK inhibitors were more expensive than crizotinib at that time. This phenomenon was also observed in the PROFILE 1014 study, where 73% of patients continued to receive crizotinib beyond disease progression for a median of 3.1 months.²⁵ In contrast, a real-world study done in the USA showed a TOT of 7 months for first-line ALK inhibitors and 9 months for second-line ALK inhibitors, which is much shorter than the PFS in clinical trials.²⁶ This is perhaps due to the patients in the USA study being older (median 61 years) compared to the patients in our study (median 53 years), with a trend towards starting second-generation ALK inhibitors earlier upon progression, as these were more freely available in the USA.

Nevertheless, randomized controlled trials of NSCLC patients with *ALK* translocations have demonstrated the superior efficacy of ALK inhibitors. Compared to chemotherapy, crizotinib significantly increased PFS in treatment-naïve (PROFILE 1014 study) and treatment-experienced (PROFILE 1007 study) patients.¹⁵ Furthermore, head-to-head trials of first- versus second-generation ALK inhibitors in the first-line setting (ALEX and J-ALEX) showed significantly better PFS with alectinib than crizotinib.¹⁵

About 20% of patients in our study had an ECOG score of 2–4, but median TOT and OS were not reached, suggesting that ALK inhibitors can be given even in patients with poor ECOG performance status. This is consistent with other studies, where ALK inhibitors have also been reported to be efficacious despite patients having poor ECOG scores (>2).^{27–30} In addition, treatment-related serious adverse events with ALK inhibitors are uncommon and at similar to or lower rates than chemotherapy, highlighting their safety,^{15,31} making them a good choice for frail patients with poor ECOG scores.

It is well known that a delayed presentation of disease followed by delayed testing can cause patients to miss the window of opportunity for efficacious treatment. In this study, a few patients with *ALK* translocations did not receive treatment because they died before test results were available. In Malaysia, sequential testing of *EGFR* mutations followed by ALK testing is a common practice in government hospitals due to laboratory-testing budget restrictions. This sequential testing approach is time-consuming and delays diagnosis. The move to adopt next-generation sequencing, which tests multiple genetic mutations simultaneously, should be encouraged, as it can be cost-effective and time-efficient with its ability to produce test results faster.³²

Rebiopsies were not performed for any patients who relapsed after an ALK inhibitor. This is probably because studies of second-line or third-line ALK inhibitors do not require rebiopsies to initiate new treatment and next-generation sequencing were expensive during the study period (US\$2500–5000 per test). However, performing a rebiopsy at relapse can provide important prognostic information and help physicians to determine the next course of treatment. In a study by Haratake et al, 2019,³³ patients who failed an ALK inhibitor and were given a subsequent ALK inhibitor based on rebiopsy results had a higher objective response rate.

Of the 1581 NSCLC patients included in the lung registry during the period of our study, 4.1% had *ALK* translocations. This figure is in keeping with international studies (4%–5%),^{1–8} but lower than another Asian study that had a prevalence of *ALK* translocation in NSCLC patients of 6.7%.^{1,2} The lower prevalence can probably be attributed to the low rate of *ALK*-translocation testing in patients with adenocarcinoma in Malaysia. This is despite *ALK* translocation being common among adenocarcinoma patients in Malaysia (13% based on earlier data in selected patients with negative *EGFR* mutations)³⁴ and ALK tests being freely available in public hospitals.³⁴ Testing for *ALK* translocation is not a priority among physicians, mainly because of the expense of ALK inhibitors, especially among government-supported patients.³⁵ The lack of access to treatment options for *ALK* mutations will affect testing rates.³⁶ Despite the small sample, the heterogeneous clinical characteristics of patients in our study and the use of different generations of ALK inhibitors

reflect the conditions of actual clinical practice, similar to a real-world Canadian study of ALK-positive patients receiving ALK inhibitors.³⁰

Conclusion

In this retrospective multi-institutional cohort of ALK-positive metastatic NSCLC patients, ALK inhibitors led to longer OS and significantly longer TOT than chemotherapy. Similar to data from clinical trials and other real-world studies, our results showed that regardless of the type or line of therapy, ALK inhibitors provided better clinical outcomes than chemotherapy. Therefore, clinicians should advocate for better access to state-of-the-art treatments, ie, ALK inhibitors, for these patients.

Cancer Management and Research

Dovepress

Publish your work in this journal

Cancer Management and Research is an international, peer-reviewed open access journal focusing on cancer research and the optimal use of preventative and integrated treatment interventions to achieve improved outcomes, enhanced survival and quality of life for the cancer patient. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/cancer-management-and-research-journal>
