Objective: Atrial fibrillation (AF) is a common arrhythmia. This study explored serum miR-29b-3p expression in AF patients and its value in predicting AF recurrence after radiofrequency catheter ablation (RFCA).

Methods: Totally 100 AF patients who underwent RFCA were enrolled, with 100 individuals without AF as controls. Serum miR-29b-3p expression in participants was determined using RT-qPCR. The correlation between miR-29b-3p and atrial fibrosis markers (FGF-21/FGF-23) was assessed by Pearson analysis. The diagnostic efficacy of serum miR-29b-3p and FGF-21/FGF-23 in predicting AF recurrence after RFCA was analyzed by the receiver operating characteristic (ROC) curves. The Kaplan-Meier method was adopted to evaluate the effect of miR-29b-3p expression on the incidence of AF recurrence after RFCA. The independent risk factors for AF recurrence after RFCA were analyzed by logistic regression analysis.

Results: Serum miR-29b-3p was poorly expressed in AF patients. After RFCA, AF patients showed elevated serum miR-29b-3p expression. Serum miR-29b-3p expression in AF patients negatively correlated with serum FGF-21 and FGF-23 concentrations. The cut-off values of serum miR-29b-3p, FGF-21, and FGF-23 in identifying AF recurrence were 0.860 (sensitivity: 100.00%, specificity: 39.71%), 222.2 pg/mL (sensitivity: 96.88%, specificity: 32.35%) and 216.3 ng/mL (sensitivity: 53.13%, specificity: 70.59%), respectively. Patients with low miR-29b-3p expression had a significantly higher incidence of AF recurrence than patients with high miR-29b-3p expression. Serum miR-29b-3p expression was one of the independent risk factors for AF recurrence after RFCA.

Conclusion: Low miR-29b-3p expression in AF patients has certain predictive values and is one of the independent risk factors for AF recurrence after RFCA.

Keywords: miR-29b-3p, atrial fibrillation, radiofrequency catheter ablation, recurrence, fibrosis marker, logistic regression analysis

Introduction

Atrial fibrillation (AF) is the most common persistent tachyarrhythmia in adults that involves a large number of health system resources. With the aging of the global population, the incidence of AF is also on the rise. In most cases, AF is the consequence of rheumatic valvular heart disease, and AF patients will experience significant atrial remodeling, which is typically manifested as atrial fibrosis. Atrial fibrosis is a complex multifactorial and patient-specific process that is also implicated in the occurrence and maintenance of AF. Furthermore, fibrosis is associated with the development and recurrence of AF. Radiofrequency catheter ablation (RFCA) and antiarrhythmic drugs are the two main therapeutic methods for AF and can effectively reduce clinical symptoms and help maintain normal sinus rhythm, and RFCA is superior to drug therapy in terms of AF recurrence rate. Even though RFCA is extensively used to treat AF patients who are refractory to drug therapy, 25% to 40% of patients will have late recurrence after intervention, and existing clinical indicators are of limited predictive values. Therefore, it is urgent to find a feasible biomarker to identify AF recurrence after RFCA.
microRNAs (miRNAs) are a class of small RNAs that are very stable in biological fluids and are considered promising non-invasive biomarkers for many pathological processes. Changes in extracellular miRNAs in the circulating blood have been detected in a large number of human pathologies, AF included. Dysregulated miRNAs can facilitate AF prevalence by deregulating transcription factors, modulating atrial excitability, and evoking atrial arrhythmias. Multiple miRNAs have the potential to cause arrhythmias and participate in different types of AF, as a regulator of cell proliferation, differentiation, and apoptosis in a variety of cancers, plays an essential role in the regulation of extracellular matrix during cardiac pathological remodeling. Studies have found that the miR-29 family plays an important role in myocardial fibrosis and inflammation by regulating related target genes. Meanwhile, miR-29 is down-regulated in atrial tissues of AF rats, and overexpression of miR-29 alleviates atrial fibrosis in AF rats. Moreover, microRNA-29b-3p (miR-29b-3p) can reduce the degree of atrial fibrosis and the expression levels of fibrosis markers and exhibits weak expression in the serum of AF patients. Besides, miR-29b-3p expression is reduced in AF patients, and IncRNA 19 drives cardiac fibroblast proliferation and collagen production by inhibiting the miR-29b-3p-VEGFA-TGF-β axis. However, the clinical significance and values of serum miR-29b-3p expression in predicting AF recurrence after RFCA have not been reported so far. This study was intended to investigate the expression of miR-29b-3p in the serum of AF patients and its predictive value for AF recurrence after RFCA.

Materials and methods
Ethics statement
This study was approved by the Academic Ethics Committee of General Hospital of Northern Theater Command. All patients were fully informed of the purpose of this study and signed informed consent before sampling. Our study complied with the Declaration of Helsinki.

Study subjects
This study prospectively enrolled 134 AF patients who were hospitalized in the General Hospital of Northern Theater Command and underwent RFCA intervention for the first time between September 2018 and August 2020 as the experimental group (AF group). After excluding 34 patients who dropped out of the experiment and were lost to follow-up, 100 patients were finally included, with an average age of (61.3 ± 6.1) years, 53 males and 47 females. AF patients were allocated to the recurrent group (N = 32) and non-recurrent group (N = 68) according to whether AF recurred within 12 months after RFCA intervention. A total of 100 individuals without AF during the same period were enrolled as controls, with an average age of (60.7 ± 6.1) years, 58 males and 42 females. The diagnosis of AF patients was made based on the diagnostic criteria of European Society of Cardiology (ESC) AF management guidelines issued in 2016.

Inclusion and Exclusion Criteria
Inclusion criteria: aged 18–75 years old with non-valvular AF; treated with RFCA for the first time; without associated sinus rhythm and severe surgical complications; with complete electrocardiogram (ECG) and preoperative examination of disease-related indicators.

Exclusion criteria: < 18 years old; left ventricular ejection fraction (LVEF) < 50%; left atrial thrombus; severe valve stenosis or incomplete heart disease; severe hepatic and renal insufficiency or heart failure; history of coronary atherosclerotic heart disease; chronic cor pulmonale; autoimmune diseases; concomitant malignant tumor; acute infection or intolerance to surgical treatment; history of RFCA intervention.

RFCA
Cardiac RFCA was performed under the guidance of the cardiac three-dimensional mapping system. Transesophageal echocardiography was performed one day before intervention to exclude left atrial appendage thrombosis. All patients received radio-frequency circumferential pulmonary vein isolation (PVI). Other procedures (including linear ablation and fragmentation potential ablation) were dependent on the assessment made by the operator. Successful intervention was defined as efferent block in all pulmonary veins and afferent block in all left atria, which was reconfirmed 30 minutes after the last PVI.
Data Collection
We recorded the clinical data of all study populations at enrollment, including age, sex, body mass index (BMI), hypertension, diabetes, smoking history, drinking history, systolic blood pressure (SBP), and diastolic blood pressure (DBP). Left atrial mean diameter (LAD) was measured using echocardiography (LOGIQ E9, Hanfei Medical Instrument, Shanghai, China). Left atrial volume index (LAVI) and LVEF were calculated using the following formulas: LAVI = left atrial volume (LAV)/body surface area, LAV = double plane area – length, and body surface area = 0.0061 × height + 0.0128 × body mass – 0.1529; LVEF = (EDV-ES) × 100%/EDV. EDV = end-diastolic volume, ES = end-systolic volume.

Enzyme-Linked Immunosorbent Assay (ELISA)
First, 5 mL of peripheral venous blood was collected from all subjects on an empty stomach on the morning of the day before RFCA and the day of the first follow-up after RFCA22 and placed in a vacuum blood collection tube without anticoagulant, followed by centrifugation at 1500 × g and 4°C for 10 minutes. Then the upper serum was isolated and stored in the refrigerator at −80°C until determination within 1 week. The expression levels of fibroblast growth factor-21 (FGF-21; 1:4, JL19322-96T, Jianglai Biotech, Shanghai, China),23 fibroblast growth factor-23 (FGF-23; 1:4, ab267652, Abcam, Cambridge, UK),24 hypersensitive C-reactive protein (hs-CRP; TW14171, Tongwei Biotechnology, Shanghai, China), and N-terminal B-type natriuretic peptide precursor (NT-proBNP; JL13111-48T, Jianglai Biotech, Shanghai, China) in serum of all subjects were determined using Human ELISA kits. The samples were incubated with coating solution in ELISA plates at 37°C for 2 hours and then incubated overnight at 4°C. Then the samples were sealed overnight at 4°C with 10% fetal bovine serum, washed, and incubated with primary antibody at 37°C for 2 hours and with secondary antibody at the same temperature for 1 hour. After the chromogenic reaction, the termination solution was added to end the reaction, and the absorbance of each well at 450 nm was measured.

Treatment and Follow-Up
After discharge, patients receiving RFCA were followed up by telephone or outpatient visits for 12 months, once every 3 months, and the 12-lead ECG and 24-h dynamic ECG were performed once a week and once a month, respectively. Antiarrhythmic drugs and anticoagulants were administered during the first three months, followed by treatment based on AF recurrence. Patients with suspected recurrent arrhythmia symptoms such as palpitations, dizziness, or chest tightness during the follow-up period should be immediately treated in local hospitals and examined by the 12-lead ECG or 24-h dynamic ECG. AF recurrence was defined as atrial tachycardia, atrial flutter, and AF of any atrial arrhythmia duration ≥ 30s recorded on the 12-lead ECG or 24-h dynamic ECG during follow-up;21 and patients who maintained sinus rhythm for 12 months after intervention were defined as having no recurrence of AF.

Reverse Transcription Quantitative Polymerase Chain Reaction (RT-qPCR)
The relative serum levels of miR-29b-3p were determined by RT-qPCR. Total RNA was extracted from the serum by TRIzol reagent (SBJ-L0055, SenBeiJia Biotech, Nanjing, China), and the concentration and purity of RNA were detected by a spectrophotometer (QuickDrop, Molecular Devices Corporation, Shanghai, China). cDNA was synthesized using a reverse transcription kit (TR102-01/02, Vazyme Biotech, Nanjing, China). U6 was used as an internal reference gene of miR-29b-3p, and primer sequences (Table 1) were obtained from Daixuan Biotech (Shanghai, China). Real-time fluorescence qPCR instrument (StepOnePlus, Sicaen Biotech, Beijing, China) was used for PCR amplification. Reaction conditions were as follows: 95°C for 30 seconds, 95°C for 10 seconds, and 60°C for 30 seconds, a total of 40 cycles. The relative expression level of miR-29b-3p standardized to that of the internal reference U6 was calculated by the 2−ΔΔCt method.

Statistical Analysis
SPSS21.0 statistical software (IBM Corp. Armonk, NY, USA) and GraphPad Prism 6.0 Software (GraphPad Software Inc., San Diego, CA, USA) were used for statistical analysis and plotting. The prior estimation of sample size was conducted using the Gpower software (Supplementary Figure 1). The Shapiro–Wilk was used to verify the normal distribution of data. Measurement data were expressed as mean ± standard error of mean (SEM) and analyzed by the t-test for data comparisons between groups. Fisher’s exact test was used for comparative analysis of categorical variables. The receiver operating characteristic (ROC) curve was used to analyze the diagnostic value of miR-29b-3p in AF and its efficacy in predicting AF recurrence after RFCA. Pearson’s coefficient was used to analyze the correlation between miR-29b-3p and the levels of fibrosis markers. The Kaplan-Meier curve was adopted to analyze the effect of miR-29b-3p on the incidence of AF recurrence after RFCA. Logistic multivariate regression analysis was used to evaluate the influencing factors of the recurrence of AF after RFCA in AF patients. Differences were considered statistically significant at \( P < 0.05 \).

Results
Comparison of General Clinical Baseline Data Between the Control Group and AF Group Before RFCA
There were no statistical differences in age, sex, BMI, hypertension, diabetes, smoking history, drinking history, SBP, DBP, LVEF, and hs-CRP between the AF group and control group (all \( P > 0.05 \)), but statistical differences were noticed in the levels of LAD, LAVI, FGF-21, FGF-23, and NT-proBNP between groups (all \( P < 0.05 \)) (Table 2).

miR-29b-3p Was Poorly Expressed in the Serum of AF Patients
The serum expression of miR-29b-3p in the AF group and control group was compared. The results manifested that the serum miR-29b-3p level was 1.0 ± 0.2 in the control group and 0.7 ± 0.2 in the AF group, which reflected that the level of miR-29b-3p in the AF group was lower than that in the control group (\( P < 0.01 \), Figure 1), indicating low expression of miR-29b-3p in the serum of AF patients.

Notes: Measurement data were expressed as mean ± standard deviation or number of cases. The comparison between two groups was analyzed by t-test, and the classification variables were analyzed by Fisher’s exact test. Differences were considered statistically significant at \( P < 0.05 \).

Abbreviations: BMI, body mass index; SBP, systolic blood pressure; DBP, diastolic blood pressure; LVEF, left ventricular ejection fraction; LAD, left atrial mean diameter; LAVI, left atrium volume index; FGF-21, fibroblast growth factor-21; FGF-23, fibroblast growth factor-23; hs-CRP, hypersensitive C-reactive protein; NT-proBNP, N-terminal B-type natriuretic peptide precursor; AF, Atrial fibrillation.
Differential Expression of Serum miR-29b-3p in AF Patients Before and After RFCA

As a major modality to treat AF, RFCA can effectively ameliorate the clinical symptoms of patients.\textsuperscript{25} RT-qPCR revealed that the expression levels of serum miR-29b-3p in AF patients before and after RFCA were 0.8 ± 0.2 and 0.7 ± 0.2, respectively, and it's evident that serum miR-29b-3p expression level was raised after RFCA, and the difference was of statistical significance ($P < 0.01$, Figure 2).

Correlation Between miR-29b-3p and Atrial Fibrosis Indicators

Atrial fibrosis is a marker of atrial remodeling in AF.\textsuperscript{5} As members of the FGF superfamily, FGF-21 is positively correlated with atrial fibrosis in patients with rheumatic heart fibrillation, and FGF-23 is closely associated with the occurrence of cardiovascular diseases.\textsuperscript{23,26,27} Moreover, FGF-21 and FGF-23 are up-regulated in the serum of AF patients and play an essential role in the prognosis of AF.\textsuperscript{23,26} To further explore the relationship between miR-29b-3p and atrial fibrosis indicators, we analyzed the correlation of miR-29b-3p with FGF-21 and FGF-23 by the Pearson method, which revealed the miR-29b-3p serum levels in the AF group were negatively correlated with serum concentrations of FGF-21 ($r = -0.797$) and FGF-23 ($r = -0.692$) (all $P < 0.001$, Figure 3A and B).

Comparison of Clinical Baseline Data Between the Non-Recurrent Group and the Recurrent Group Before RFCA

AF patients were assigned to the non-recurrent AF group (N = 68) and recurrent AF group (N = 32) according to whether AF recurred within 12 months after RFCA. We compared the clinical indicators between the recurrent group and non-recurrent group and discovered that there was no significant difference in age, sex, BMI, hypertension, diabetes, smoking history, drinking history, and levels of LVEF, LAD, hs-CRP, and NT-proBNP between the recurrent group and non-recurrent group (all $P > 0.05$), while there were statistical differences in LAVI, FGF-21, and FGF-23 levels (all $P < 0.05$). The specific results are shown in Table 3.

Poor Expression of miR-29b-3p Predicted a High Risk of AF Recurrence After RFCA

To ascertain whether the expression level of miR-29b-3p is related to the recurrence of AF, we measured miR-29b-3p expression level in the serum of AF patients in the non-recurrent and recurrent groups by RT-qPCR. The results

Figure 1 Expression levels of miR-29b-3p in the serum of AF patients. The serum expression of miR-29b-3p was determined by RT-qPCR. The t-test was used for data comparisons between two groups. *** $P < 0.001$. 

https://doi.org/10.2147/CIA.S450292

DovePress
uncovered that the relative level of miR-29b-3p in the serum of patients in the recurrent group was visibly lower than that of patients in the non-recurrent group ($P < 0.01$) (Figure 4A). We further plotted the ROC curve of serum miR-29b-3p for the evaluation of recurrence in AF patients after RFCA (Figure 4B) and found that the area under the curve (AUC) was 0.716, with a cut-off value of 0.860 (sensitivity: 100.00%, specificity: 39.71%). Briefly, the serum miR-29b-3p level < 0.860 can assist in predicting recurrence after RFCA in AF patients. What’s more, the AUC of serum FGF-21 and FGF-23 for the prediction of AF recurrence was 0.637 (cut-off value: 222.2 pg/mL, sensitivity: 96.88%, specificity: 32.35%) and 0.625 (cut-off value: 216.3 ng/mL, sensitivity: 53.13%, specificity: 70.59%) (Figure 4C and D).
Additionally, AF patients were divided into the low expression group (miR-29b-3p < 0.691, N=50) and the high expression group (miR-29b-3p > 0.691, N=50) according to the median expression level of serum miR-29b-3p (0.691) in 100 AF patients, and the incidence of AF recurrence after RFCA was compared between the two groups. There were differences in the prognosis between the two groups ($\chi^2 = 3.869$, $P < 0.05$), and the incidence of recurrence of AF after RFCA in the low expression group was 38.00%, higher than that in the high expression group (26.00%) (Table 4). In addition, Kaplan-Meier analysis showed that the curve shifted left in the low expression group ($P < 0.05$, Figure 4E), indicating that the cumulative incidence of AF recurrence after RFCA was higher in the low expression group during the same follow-up period. Taken together, the low expression of serum miR-29b-3p predicted a high risk of AF recurrence after RFCA.

**Low Expression of miR-29b-3p Was One of the Independent Risk Factors for AF Recurrence After RFCA**

To accurately evaluate the effects of miR-29b-3p on AF recurrence after RFCA, we analyzed the independent correlation between miR-29b-3p expression level and AF. With AF recurrence as the dependent variable, the independent variables (including LAVI, FGF-21, FGF-23, and NT-proBNP) ($P \leq 0.1$) and miR-29b-3p were included in the binary multivariate logistics regression analysis model according to the analysis results in Table 3. The logistics regression model showed that after adjusting the indicators LAVI, low expression of miR-29b-3p resulted in an increased risk of AF after RFCA and was one of the independent risk factors for AF recurrence after RFCA [$P = 0.027$, odds ratios = 0.002, 95% confidence interval (CI): 0.000–0.494] (Table 5).

**Discussion**

AF is a multifactorial disease that normally occurs in response to underlying cardiac abnormalities and is supported by changes in the electrophysiological, anatomical, and structural properties, generally referred to as atrial remodeling. Recently, miRNAs have been confirmed to play an essential role in the pathophysiology of AF by regulating the
This study demonstrated that the low expression of miR-29b-3p in AF patients has certain predictive values in AF recurrence after RFCA, and is an independent risk factor for the recurrence of AF after RFCA. Mounting evidence indicates that miRNA expression level is correlated with the occurrence and severity of AF. A previous study has shown that miR-29b is down-regulated in the plasma of AF patients. Our study also showed the same expression trend of miR-29b-3p in the enrolled AF patients as the findings of our peers. RFCA may cure AF for some symptomatic patients. Our results presented that serum miR-29b-3p expression was elevated in AF patients after RFCA. Atrial fibrosis is a marker of atrial remodeling and is involved in the occurrence and maintenance of AF. Meanwhile, miRNAs play an important role in the pathophysiology of fibrosis development at the ventricular and atrial levels. In particular, miR-29b-3p is considered to be an anti-fibrotic factor, and overexpression of miR-29b-3p may inhibit cardiac fibrosis and systemic sclerosis. Moreover, changes in serum expression levels of FGF-21 and FGF-23, biomarkers of atrial fibrosis, are of great significance in predicting the occurrence of AF. The serum expression levels of FGF-21 and FGF-23 in AF patients are positively correlated with the degree of atrial fibrosis. In our present study,

the serum expression level of miR-29b-3p in AF patients was negatively correlated with the concentration of FGF-21 and FGF-23. In brief, miR-29b-3p was correlated with atrial fibrosis.

RFCA is an effective method for AF treatment, but the relatively high rate of AF recurrence after RFCA is a long-standing problem. miRNAs play a regulatory role in the recurrence of AF after RFCA. As expected, serum miR-29b-3p was poorly expressed in patients with AF recurrence, along with diminished LAVI and FGF-23 levels. Circulating miRNAs are identified as potential biomarkers for AF since they can be detected in the plasma or serum with high sensitivity and specificity. Furthermore, we plotted the ROC curves of miR-29b-3p in diagnosing AF patients to evaluate its diagnostic efficacy. Interestingly, the AUC of miR-29b-3p was 0.716 (the cut-off value: 0.860, 100.00% sensitivity, 39.71% specificity), higher than that of FGF-21 and FGF-23. Previously, miR-409-3p, miR-630, miR-146b-5p, and miR-367 alone have potential diagnostic values in differentiating AF patients from healthy controls. Our study initially highlighted that serum miR-29b-3p expression levels < 0.860 can assist in predicting the recurrence of AF after RFCA.

In addition, the incidence of AF recurrence after RFCA was higher in patients with low miR-29b-3p expression than that in patients with high miR-29b-3p expression, and the cumulative incidence of recurrence after RFCA was higher in patients with low miR-29b-3p expression. Although many studies have shown down-regulation of miR-29b in AF, there are little data on the association between miR-29b-3p and AF ablation outcomes. Circulating miR-21 is associated with ablation success in patients with persistent AF who underwent catheter ablation. Our study illustrated that poor expression of miR-29b-3p predicted a high risk of AF recurrence after RFCA. Furthermore, after adjusting LAVI, poor expression of miR-29b-3p led to an increased risk of AF after RFCA and was one of the independent risk factors for AF after RFCA. These results were suggestive of the functionality of miR-29b-3p on AF recurrence after RFCA.

In conclusion, as a prospective study, this study measured the serum expression levels of miR-29b-3p in AF patients and explored the predictive effect of miR-29b-3p expression level on AF recurrence after RFCA, providing a new entry point for clinical condition judgment and recurrence prediction of AF. However, the number of cases and events included in this study was limited, and the regulatory mechanism of miR-29b-3p in AF was not thoroughly discussed. In the future, a multi-center prospective study will be conducted to expand the sample size with matched controls to increase the credibility of the results and clarify the diagnostic and prognostic evaluation capabilities of miR-29b-3p. In addition, the expression levels of miR-29b-3p in cells of AF patients could be determined to study their effects on cell proliferation, apoptosis, and cell cycle.
